This reference guide describes Apache Solr version 3.4, an open source solution for search. You can download Apache Solr 3.4 at www.lucidimagination.com/downloads. This guide contains the following sections:

[Getting Started](#): Installing Solr and getting it running for the first time

[Using the Solr Administration User Interface](#): How to use the built-in UI

[Documents, Fields, and Schema Design](#): Designing the index for optimal retrieval

[Understanding Analyzers, Tokenizers, and Filters](#): Setting up Solr to handle your content

[Indexing and Basic Data Operations](#): Indexing your content

[Searching](#): Ways to improve the search experience for your users

[The Well-Configured Solr Instance](#): Optimal settings to keep the system running smooth

[Managing Solr](#): Web containers, logging and backups

[Scaling and Distribution](#): Best practices for increasing system capacity

[Client APIs](#): Clients that can be used to provide search interfaces for users

Solr and Lucene

Solr makes it easy for programmers to develop sophisticated, high-performance search applications with advanced features such as faceting (arranging search results in columns with numerical counts of key terms). Solr builds on another open source search technology: Lucene, a Java library that provides indexing and search technology, as well as spellchecking, hit highlighting and advanced analysis/tokenization capabilities. Both Solr and Lucene are managed by the Apache Software Foundation (www.apache.org).

The Lucene search library currently ranks among the top 15 open source projects and is one of the top 5 Apache projects, with installations at over 4,000 companies. Lucene/Solr downloads have grown nearly ten times over the past three years, with a current run-rate of over 6,000 downloads a day. The Solr search server, which provides application builders a ready-to-use search platform on top of the Lucene search library, is the fastest growing Lucene sub-project. Apache Lucene/Solr offers an attractive alternative to the proprietary licensed search and discovery software vendors.

Lucid Imagination

Lucid Imagination is the first commercial company exclusively dedicated to Apache Lucene/Solr open source technology. To learn more about Lucid Imagination, please see www.lucidimagination.com. The Lucid Imagination founding team consists of several key contributors and committers to the Lucene project, as well as experts in enterprise search software development.

We provide the planet's best search solution development platforms built on the power of Solr/Lucene open source search. LucidWorks Enterprise makes the power of Solr/Lucene open source search more accessible to the broad range of application developers and slashes the learning curve for search solution development. Unlike "black box" products, LucidWorks Enterprise allows organizations of all sizes and types to continuously tune their search to fit the ongoing needs of their users and achieve a consistently lower cost of growth.

Lucid Imagination also offers free software for developers, documentation, commercial-grade support, high-level consulting, and comprehensive training. Customers include AT&T, Sears, Ford, Verizon, Cisco, Zappos, Raytheon, The Guardian, The Smithsonian Institution, Salesforce.com, The MotleyFool, Macy's, Qualcomm, Taser, eHarmony, and many other household names around the world.

About This Guide

This guide describes all of the important features and functions of Apache Solr 3.4. It is free to download from [Lucid Imagination](#).

Designed to provide high-level documentation, this guide is intended to be more encyclopedic and less of a cookbook. It is structured to address a broad spectrum of needs, ranging from new developers getting started to well-experienced developers extending their application or troubleshooting. It will be of use at any point in the application life cycle, for whenever you need authoritative information about Solr.

The material as presented assumes that you are familiar with some basic search concepts and that you can read XML. It does not assume that you are a Java programmer, although knowledge of Java is helpful when working directly with Lucene or when developing custom extensions to a Lucene/Solr installation.

This guide includes the following sections:

- [Getting Started](#): This section guides you through the installation and setup of Solr.
- [Using the Solr Administration User Interface](#): This section introduces the Solr Web-based user interface. From your browser you can view configuration files, submit queries, view logfile settings and Java environment settings, and monitor and control distributed configurations.
- [Documents, Fields, and Schema Design](#): This section describes how Solr organizes its data for indexing. It explains how a Solr schema defines the fields and field types which Solr uses to organize data within the document files it indexes.
- [Understanding Analyzers, Tokenizers, and Filters](#): This section explains how Solr prepares text for indexing and searching. Analyzers parse text and produce a stream of tokens, lexical units used for indexing and searching. Tokenizers break field data down into tokens. Filters perform other transformational or selective work on token streams.
- [Indexing and Basic Data Operations](#): This section describes the indexing process and basic index operations, such as commit, optimize, and rollback.
- [Searching](#): This section presents an overview of the search process in Solr. It describes the main components used in searches, including request handlers, query parsers, and response writers. It lists the query parameters that can be passed to Solr, and it describes features such as boosting and faceting, which can be used to fine-tune search results.

- [The Well-Configured Solr Instance](#): This section discusses performance tuning for Solr. It begins with an overview of the `solrconfig.xml` file, then tells you how to configure cores with `solr.xml`, how to configure the Lucene index writer, and more.
- [Managing Solr](#): This section discusses important topics for running and monitoring Solr. It describes running Solr in the Apache Tomcat servlet runner and Web server. Other topics include how to back up a Solr instance, and how to run Solr with Java Management Extensions (JMX).
- [Scaling and Distribution](#): This section tells you how to grow a Solr distribution by dividing a large index into sections called shards, which are then distributed across multiple servers, or by replicating a single index across multiple services.
- [Client APIs](#): This section tells you how to access Solr through various client APIs, including JavaScript, JSON, and Ruby.

The default port configured for Solr during the install process is 8983. The samples, URLs and screenshots in this guide may show different ports, because the port number that Solr uses is configurable. If you have not customized your installation of Solr, please make sure that you use port 8983 when following the examples, or configure your own installation to use the port numbers shown in the examples. For information about configuring port numbers used by Tomcat or Jetty, see [Managing Solr](#).

Further Assistance

In addition to providing this Reference Guide for Solr, Lucid Imagination offers other helpful documentation and tips on its Web site, www.lucidimagination.com. Visit the Web site for:

- Technical Notes on special topics
- White Papers about important search topics and methodologies
- Blog posts about the latest news and events of interest to the Lucene and Solr communities
- Podcasts presenting Lucene and Solr tutorials, as well as interview with Lucene and Solr committers and customers

There is also a very active user community around Solr and Lucene. The solr-user mailing list is a great resource for questions. To view the archives or subscribe to the list, see http://mail-archives.apache.org/mod_mbox/lucene-solr-user/.

Lucid Imagination has created a search index for all things Lucene and Solr, called [LucidFind](#). Content to be found there includes: All messages to the mailing lists for Lucene and Solr, the full contents of the Lucene/Solr websites, the Lucene/Solr documentation wikis, all of the Lucid Imagination published content, and mailing lists, websites and wikis for a host of related Apache projects.

For more information about services or software offered by Lucid Imagination, [contact us online](#) or at:

Lucid Imagination
3800 Bridge Parkway, Suite 101
Redwood City, CA 94065

Tel: 650.353.4057
Fax: 650.620.9540

Getting Started

This section helps you get Solr up and running quickly, and introduces you to the basic Solr architecture and features. It covers the following topics:

[Installing Solr](#): A walkthrough of the Solr installation process.

[Running Solr](#): An introduction to running Solr. Includes information on starting up the servers, adding documents, and running queries.

[A Quick Overview](#): A high-level overview of how Solr works.

[A Step Closer](#): An introduction to Solr's home directory and configuration options.

Installing Solr

This section describes how to install Solr. You can install Solr anywhere that a suitable Java Runtime Environment (JRE) is available, as detailed below. Currently this includes Linux, OS X, and Microsoft Windows. The instructions in this section should work for any platform, with a few exceptions for Windows as noted.

Got Java?

You will need the Java Runtime Environment (JRE) version 1.5 or higher, although 1.6 is highly recommended. At a command line, check your Java version like this:

```
$ *java -version*
java version "1.6.0_0"
IcedTea6 1.3.1 (6b12-0ubuntu6.1) Runtime Environment (build 1.6.0_0-b12)
OpenJDK Client VM (build 1.6.0_0-b12, mixed mode, sharing)
```

The output will vary, but you need to make sure you have version 1.5 or higher. If you don't have the required version, or if the java command is not found, download and install the latest version from Sun at <http://java.sun.com/javase/downloads/>.

Installing Solr

Solr is available from the Lucid Imagination website at <http://www.lucidimagination.com/Downloads>.

For Linux/Unix/OSX systems, download the .gzip file. For Microsoft Windows systems, download the .zip file.

Solr runs inside a Java servlet container such as Tomcat, Jetty, or Resin. The Solr distribution includes a working demonstration server in the `Example` directory that runs in Jetty. You can use the example server as a template for your own installation, whether or not you are using Jetty as your servlet container. For more information about the demonstration server, see the [Solr Tutorial](#).

To install Solr

1. Unpack the Solr distribution to your desired location.
2. Stop your Java servlet container.
3. Copy the `solr.war` file from the Solr distribution to the `webapps` directory of your servlet container. Do not change the name of this file: it must be named `solr.war`.
4. Copy the Solr Home directory `apache-solr-3.4.0/example/solr/` from the distribution to your desired Solr Home location.

5. Start your servlet container, passing to it the location of your Solr Home in one of these ways:
 - Set the Java system property `solr.solr.home` to your Solr Home. (for example, using the example jetty setup: `java -Dsolr.solr.home=/some/dir -jar start.jar`).
 - Configure the servlet container so that a JNDI lookup of `java:comp/env/solr/home` by the Solr webapp will point to your Solr Home.
 - Start the servlet container in the directory containing `./solr`: the default Solr Home is `solr` under the JVM's current working directory (`$CWD/solr`).

To confirm your installation, go to the [Solr Admin page](http://_hostname_:8983/solr/admin/) at `http://_hostname_:8983/solr/admin/`. Note that your servlet container may have started on a different port: check the documentation for your servlet container to troubleshoot that issue. Also note that if that port is already in use, Solr will not start. In that case, shut down the servlet container running on that port, or change your Solr port.

For more information about installing and running Solr on different Java servlet containers, see the [SolrInstall](#) page on the [Solr Wiki](#).

Running Solr

This section describes how to run Solr with an example schema, how to add documents, and how to run queries.

Start the Server

If you didn't start Solr after installing it, you can start it by running `start.jar` from the Solr example directory.

```
$ java -jar start.jar
```

If you are running Windows, you can start the Web server by running `start.bat` instead.

```
C:\Applications\Solr\example > start.bat
```

That's it! Solr is running. If you need convincing, use a Web browser to see the Admin Console.

`http://localhost:8983/solr/admin`

Solr Admin (example)
drews-macbook:8983
cwd=/Users/drewwheeler/apache-solr-3.4.0/example SolrHome=solr/
HTTP caching is OFF

Solr [SCHEMA] [CONFIG] [ANALYSIS] [SCHEMABROWSER]
[STATISTICS] [INFO] [DISTRIBUTION] [PING] [LOGGING]

The Solr Admin interface.

If Solr is not running, your browser will complain that it cannot connect to the server. Check your port number and try again.

Add Documents

Solr is built to find documents that match queries. Solr's schema provides an idea of how content is structured (more on the schema [later](#)), but without documents there is nothing to find. Solr needs input before it can do anything.

You may want to add a few sample documents before trying to index your own content. The Solr installation comes with example documents located in the `example/exampledocs` directory of your installation.

In the `exampledocs` directory is the SimplePostTool, a Java-based command line tool, `post.jar`, which can be used to index the documents. Do not worry too much about the details for now. The [Indexing and Basic Data Operations](#) section has all the details on indexing.

To see some information about the usage of `post.jar`, use the `-help` option.

```
$ java -jar post.jar -help
```

The SimplePostTool is a simple command line tool for POSTing raw XML to a Solr port. XML data can be read from files specified as command line arguments, as raw command line `arg` strings, or via STDIN.

Examples:

```
java -Ddata=files -jar post.jar *.xml
java -Ddata=args -jar post.jar '<delete><id>42</id></delete>'
java -Ddata=stdin -jar post.jar < hd.xml
```

Other options controlled by System Properties include the Solr URL to POST to, and whether a commit should be executed. These are the defaults for all System Properties:

```
-Ddata=files
-Durl=http://localhost:8983/solr/update
-Dcommit=yes
```

Go ahead and add all the documents in the directory as follows:

```
$ *java -Durl=http://localhost:8983/solr/update -jar post.jar *.xml*
SimplePostTool: version 1.2
SimplePostTool: WARNING: Make sure your XML documents are encoded in UTF-8, other
encodings are not currently supported
SimplePostTool: POSTing files to http://10.211.55.8:8983/solr/update..
SimplePostTool: POSTing file hd.xml
SimplePostTool: POSTing file ipod_other.xml
SimplePostTool: POSTing file ipod_video.xml
SimplePostTool: POSTing file mem.xml
SimplePostTool: POSTing file monitor.xml
SimplePostTool: POSTing file monitor2.xml
SimplePostTool: POSTing file mp500.xml
SimplePostTool: POSTing file sd500.xml
SimplePostTool: POSTing file solr.xml
SimplePostTool: POSTing file spellchecker.xml
SimplePostTool: POSTing file utf8-example.xml
SimplePostTool: POSTing file vidcard.xml
SimplePostTool: COMMITting Solr index changes..
$
```

That's it! Solr has indexed the documents contained in the files.

Ask Questions

Now that you have indexed documents, you can perform queries. The simplest way is by building a URL that includes the query parameters. This is exactly the same as building any other HTTP URL.

For example, the following query searches all document fields for "video":

```
http://localhost:8983/solr/select?q=video
```

Notice how the URL includes the host name (`localhost`), the port number where the server is listening (`8983`), the application name (`solr`), the request handler for queries (`select`), and finally, the query itself (`q=video`).

The results are contained in an XML document, which you can examine directly by clicking on the link above. The document contains two parts. The first part is the `responseHeader`, which contains information about the response itself. The main part of the reply is in the `result` tag, which contains one or more `doc` tags, each of which contains fields from documents that match the query. You can use standard XML transformation techniques to mold Solr's results into a form that is suitable for displaying to users. Alternatively, Solr can output the results in JSON, PHP, Ruby and even user-defined formats.

Just in case you are not running Solr as you read, the following screen shot shows the result of a query (the next example, actually) as viewed in Mozilla Firefox. The top-level response contains a 1st named `responseHeader` and a result named `response`. Inside result, you can see the three docs that represent the search results.

```

- <response>
- <lst name="responseHeader">
  <int name="status">0</int>
  <int name="QTime">0</int>
  - <lst name="params">
    <str name="q">video</str>
  </lst>
</lst>
- <result name="response" numFound="3" start="0">
- <doc>
  - <arr name="cat">
    <str>electronics</str>
    <str>music</str>
  </arr>
  - <arr name="features">
    <str>iTunes, Podcasts, Audiobooks</str>
    - <str>
      Stores up to 15,000 songs, 25,000 photos, or 150 hours of video
    </str>
    - <str>
      2.5-inch, 320x240 color TFT LCD display with LED backlight
    </str>
    <str>Up to 20 hours of battery life</str>
    - <str>
      Plays AAC, MP3, WAV, AIFF, Audible, Apple Lossless, H.264 video
    </str>
    - <str>
      Notes, Calendar, Phone book, Hold button, Date display, Photo wallet, Built-in games, JPEG photo playback, Upgradeable
      firmware, USB 2.0 compatibility, Playback speed control, Rechargeable capability, Battery level indication
    </str>
  </arr>
  <str name="id">MA147LL/A</str>
  <bool name="inStock">>true</bool>
  <str name="includes">earbud headphones, USB cable</str>
  <str name="manu">Apple Computer Inc.</str>
  <date name="manufacturedate_dt">2005-10-12T08:00:00Z</date>
  <str name="name">Apple 60 GB iPod with Video Playback Black</str>
  <int name="popularity">10</int>
  <float name="price">399.0</float>
  <str name="store">37.7752,-100.0232</str>
  <float name="weight">5.5</float>
</doc>
- <doc>

```

An XML response to a query.

Once you have mastered the basic idea of a query, it is easy to add enhancements to explore the query syntax. This one is the same as before but the results only contain the ID, name, and price for each returned document. If you don't specify which fields you want, all of them are returned.

```
http://localhost:8983/solr/select?q=video&fl=id,name,price
```

Here is another example which searches for "black" in the name field only. If you do not tell Solr which field to search, it will search default fields, as specified in the schema.

```
http://localhost:8983/solr/select?q=name:black
```

You can provide ranges for fields. The following query finds every document whose price is between \$0 and \$400.

```
http://localhost:8983/solr/select?q=price:0%20TO%20400&fl=id,name,price
```

[Faceted browsing](#) is one of Solr's key features. It allows users to narrow search results in ways that are meaningful to your application. For example, a shopping site could provide facets to narrow search results by manufacturer or price.

Faceting information is returned as a third part of Solr's query response. To get a taste of this power, take a look at the following query. It adds `facet=true` and `facet.field=cat`.

```
http://localhost:8983/solr/select?q=price:0%20TO%20400&fl=id,name,price&facet=true&f
```

In addition to the familiar `responseHeader` and `response` from Solr, a `facet_counts` element is also present. Here is a view with the `responseHeader` and `response` collapsed so you can see the faceting information clearly.

```

- <response>
- <lst name="responseHeader">
  <int name="status">0</int>
  <int name="QTime">1</int>
  - <lst name="params">
    <str name="q">video</str>
  </lst>
</lst>
- <result name="response" numFound="3" start="0">
- <doc>
  - <arr name="cat">
    <str>electronics</str>
    <str>music</str>
  </arr>
  - <arr name="features">
    <str>iTunes, Podcasts, Audiobooks</str>
    - <str>
      Stores up to 15,000 songs, 25,000 photos, or 150 hours of video
    </str>
    - <str>
      2.5-inch, 320x240 color TFT LCD display with LED backlight
    </str>
    <str>Up to 20 hours of battery life</str>
    - <str>
      Plays AAC, MP3, WAV, AIFF, Audible, Apple Lossless, H.264 video
    </str>
    - <str>
      Notes, Calendar, Phone book, Hold button, Date display, Photo wallet, Built-in games, JPEG photo playback, Upgradeable
      firmware, USB 2.0 compatibility, Playback speed control, Rechargeable capability, Battery level indication
    </str>
  </arr>
  <str name="id">MA147LL/A</str>
  <bool name="inStock">true</bool>
  <str name="includes">earbud headphones, USB cable</str>
  <str name="manu">Apple Computer Inc.</str>
  <date name="manufacturedate_dt">2005-10-12T08:00:00Z</date>
  <str name="name">Apple 60 GB iPod with Video Playback Black</str>
  <int name="popularity">10</int>
  <float name="price">399.0</float>
  <str name="store">37.7752,-100.0232</str>
  <float name="weight">5.5</float>
</doc>
</doc>

```

An XML Response with faceting.

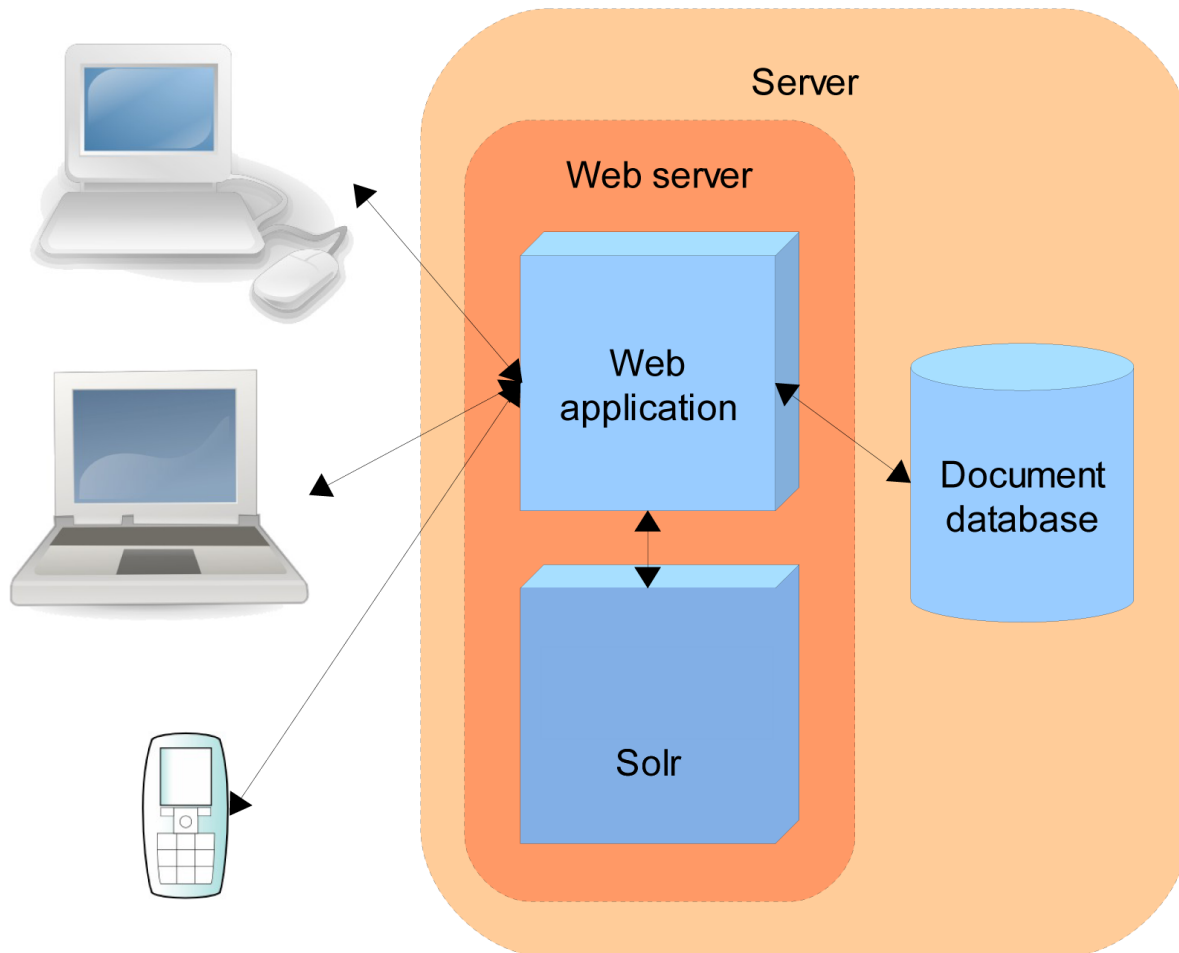

The facet information shows how many of the query results have each possible value of the cat field. You could easily use this information to provide users with a quick way to narrow their query results. You can filter results by adding one or more filter queries to the Solr request. Here is a request further constraining the request to documents with a category of "software".

`http://localhost:8983/solr/select?q=price:0%20TO%20400&fl=id,name,price&facet=true&f`

A Quick Overview

Having had some fun with Solr, you will now learn about all the cool things it can do.

Here is a typical configuration:

In the scenario above, Solr runs alongside another application in a Web server like Tomcat. For example, an online store application would provide a user interface, a shopping cart, and a way to make purchases. The store items would be kept in some kind of database.

Solr makes it easy to add the capability to search through the online store through the following steps:

1. Define a *schema*. The schema tells Solr about the contents of documents it will be indexing. In the online store example, the schema would define fields for the product name, description, price, manufacturer, and so on. Solr's schema is powerful and flexible and allows you to tailor Solr's behavior to your application. See [Documents, Fields, and Schema Design](#) for all the details.

2. Deploy Solr to your application server.
3. Feed Solr the document for which your users will search.
4. Expose search functionality in your application.

Because Solr is based on open standards, it is highly extensible. Solr queries are RESTful, which means, in essence, that a query is a simple HTTP request URL and the response is a structured document: mainly XML, but it could also be JSON, CSV, or some other format. This means that a wide variety of clients will be able to use Solr, from other web applications to browser clients, rich client applications, and mobile devices. Any platform capable of HTTP can talk to Solr. See [Client APIs](#) for details on client APIs.

Solr is based on the Apache Lucene project, a high-performance, full-featured search engine. Solr offers support for the simplest keyword searching through to complex queries on multiple fields and faceted search results. [Searching](#) has more information about searching and queries.

If Solr's capabilities are not impressive enough, its ability to handle very high-volume applications should do the trick.

A relatively common scenario is that you have so many queries that the server is unable to respond fast enough to each one. In this case, you can make copies of an index. This is called replication. Then you can distribute incoming queries among the copies in any way you see fit. A round-robin mechanism is one simple way to do this.

Another useful technique, less common than replication, is sharding. If you have so many documents that you simply cannot fit them all on a single box for RAM or index size reasons, you can split an index into multiple pieces, called *shards*. Each shard lives on its own physical server. An incoming query is sent to all the shard servers, which respond with matching results.

If you are fortunate enough to have huge numbers of documents and users, you might need to combine the techniques of sharding and replication. In this case, you create some number of shards, then replicate the shards. Incoming queries are sent to one server for each shard.

Distributed + Replication

For full details on sharding and replication, see [Scaling and Distribution](#).

Best of all, this talk about high-volume applications is not just hypothetical: some of the famous Internet sites that use Solr today are Macy's, EBay, and Zappo's.

For more information, take a look at <https://wiki.apache.org/solr/PublicServers>.

A Step Closer

You already have some idea of Solr's schema. This section describes Solr's home directory and other configuration options.

When Solr runs in an application server, it needs access to a home directory. The home directory contains important configuration information and is the place where Solr will store its index.

The crucial parts of the Solr home directory are shown here:

```
<solr-home-directory>/
  solr.xml
  conf/
    solrconfig.xml
    schema.xml
  data/
```

You supply `solr.xml`, `solrconfig.xml`, and `schema.xml` to tell Solr how to behave. By default, Solr stores its index inside `data`.

`solr.xml` specifies configuration options for your Solr core, and also allows you to configure multiple cores. For more information on `solr.xml` see [The Well-Configured Solr Instance](#).

`solrconfig.xml` controls high-level behavior. You can, for example, specify an alternate location for the data directory. For more information on `solrconfig.xml`, see [The Well-Configured Solr Instance](#).

`schema.xml` describes the documents you will ask Solr to index. Inside `schema.xml`, you define a document as a collection of fields. You get to define both the field types and the fields themselves. Field type definitions are powerful and include information about how Solr processes incoming field values and query values. For more information on `schema.xml`, see [Documents, Fields, and Schema Design](#).

Using the Solr Administration User Interface

This section discusses the Solr Administration User Interface ("Admin UI"). It covers the following topics:

[Overview of the Solr Admin UI](#): An introduction to the Solr Administration User Interface.

[The Solr Section](#): Detailed information about the Solr section of the Admin UI.

[The App Server Section](#): Detailed information about the App Server section of the Admin UI.

[The Make a Query Section](#): Detailed information about the Make A Query section of the Admin UI.

[The Assistance Section](#): Detailed information about the Assistance section of the Admin UI.

Overview of the Solr Admin UI

Solr features a Web interface that makes it easy for Solr administrators and programmers to:

- view [Solr configuration](#) details
- run [queries and analyze](#) document fields in order to fine-tune a Solr configuration
- access [online documentation](#) and other help

Users access the Admin UI through the `solr/admin/` page, which by default is located at `http://hostname:8983/solr/admin/`. The name of the Solr installation's top directory appears in parentheses at the top of the page.

Solr Admin (example)
 drews-macbook:8983
 cwd=/Users/drewwheeler/apache-solr-3.4.0/example SolrHome=solr/
 HTTP caching is OFF

Solr [SCHEMA] [CONFIG] [ANALYSIS] [SCHEMA BROWSER]
 [STATISTICS] [INFO] [DISTRIBUTION] [PING] [LOGGING]

App server: [JAVA PROPERTIES] [THREAD DUMP]

Make a Query [FULL INTERFACE]
 Query String:

Assistance [DOCUMENTATION] [ISSUE TRACKER] [SEND EMAIL]
 [SOLR QUERY SYNTAX]
 Current Time: Fri Sep 30 09:58:15 PDT 2011
 Server Start At: Thu Sep 29 12:40:47 PDT 2011

The Solr Admin UI.

The main page of the Admin UI is divided into three parts:

- a section for exploring the Solr server and its application server
- a section for running queries
- a section on getting assistance, either by accessing documentation or the Solr issue tracker, or by contacting the Apache Solr project team

If you are running Solr on a Macintosh, you should access the Admin UI in a browser other than Safari, because Safari will not display raw XML content, such as the contents of the Solr `schema.xml` file.

Configuring the Admin UI in `solrconfig.xml`

You can configure the Solr Admin UI by editing the file `solrconfig.xml`. The `<admin>` block in the `solrconfig.xml` file determines:

- Which files the Web interface can access
- How the interface's PING link should call the ping command
- Whether or not the interface displays the ENABLE/DISABLE link in the App Server section

In its default configuration, which is shown below, the Admin UI is configured to access `solrconfig.xml` and `schema.xml`. It also specifies the parameters the interface should pass to the ping command when a user clicks on the interface's PING link. It also creates a file called `server-enabled`, which will be created or deleted depending on the server's status.

```
<admin>
  <defaultQuery>solr</defaultQuery>
  <gettableFiles>
    solrconfig.xml
    schema.xml
  </gettableFiles>
  <pingQuery>q=solr&version=2.0&start=0&rows=0</pingQuery>

  <!-- configure a healthcheck file for servers behind a loadbalancer -->

  <healthcheck type="file">server-enabled</healthcheck>
</admin>
```

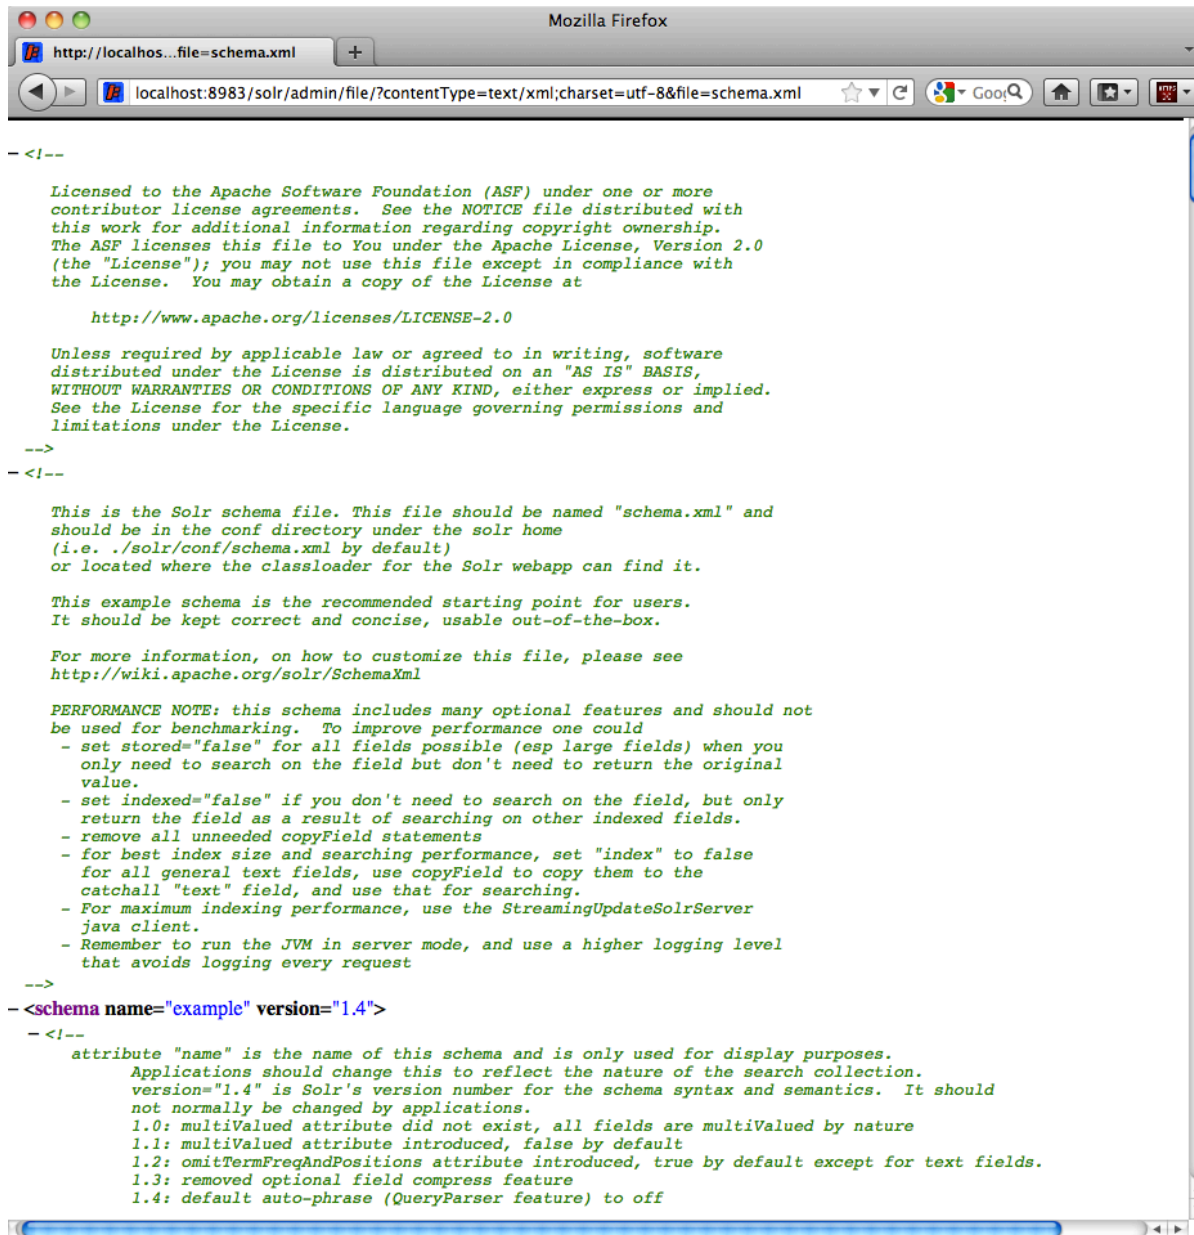

The Solr Section

The Solr section of the Admin UI includes the following links.

Link	Description
SCHEMA	Displays the <code>schema.xml</code> file, a configuration file that describes the data to be indexed and searched.
CONFIG	Displays the <code>solrconfig.xml</code> file, a file that contains most of the parameters for configuring Solr itself.
ANALYSIS	Displays a Field Analysis form, which is useful for testing the behavior of Analyzers, Tokenizers, and TokenFilters on different fields.
SCHEMA BROWSER	Displays a dynamic HTML interface for exploring the <code>schema.xml</code> settings of the Solr server.
STATISTICS	Displays configuration details and statistics about the following aspects of the Solr server: <code>CORECACHEQUERY</code> , <code>handlersUPDATE</code> , <code>handlersHIGHLIGHTINGOTHER</code> (reserved for future use). The Solr server continually updates the statistics presented on this page.
INFO	Displays startup-time data about the following categories: <code>CORECACHEQUERY</code> , <code>handlersUPDATE</code> , <code>handlersOTHER</code> (reserved for future use). Unlike the statistics presented on the <code>STATISTICS</code> page, the statistics presented on the <code>INFO</code> page do not change after startup.
DISTRIBUTION	Displays details about a distributed Solr configuration, if the Solr server is configured as either a Master or Slave server. On a Master instance, each row displays the name of the slave and the snapshots the slave has retrieved. On a Slave instance, the page displays a single line showing the name of its last attempt to retrieve a snapshot from its master.
PING	Runs the ping command against the Solr server in order to confirm that the server is running and responsive to network requests. If the command is successful, it returns <code>HTTP 200</code> to the browser but displays nothing. If unsuccessful, the command returns <code>HTTP 500</code> (an error) and displays an exception message.
LOGGING	Displays an interactive form for setting and viewing the effective logging levels of the JDK Log hierarchy.

Displaying the Solr Schema

To display the Solr `schema.xml` file in your browser, click the `SCHEMA` link. The browser will then display then `schema.xml` file, as shown in the image below.

The `schema.xml` file.

For more information on the `schema.xml` file, see [Documents, Fields, and Schema Design](#).

Displaying the Solr Configuration File

To display the `solrconfig.xml` file, click the `CONFIG` link. Solr displays the file in the browser, as shown below.

```

  limitations under the License.
-->
- <!--
  For more details about configurations options that may appear in
  this file, see http://wiki.apache.org/solr/SolrConfigXml.
-->
- <config>
- <!--
  In all configuration below, a prefix of "solr." for class names
  is an alias that causes solr to search appropriate packages,
  including org.apache.solr.(search|update|request|core|analysis)

  You may also specify a fully qualified Java classname if you
  have your own custom plugins.

-->
- <!--
  Set this to 'false' if you want solr to continue working after
  it has encountered a severe configuration error.  In a
  production environment, you may want solr to keep working even
  if one handler is mis-configured.

  You may also set this to false using by setting the system
  property:

  -Dsolr.abortOnConfigurationError=false

-->
<abortOnConfigurationError>${solr.abortOnConfigurationError:true}</abortOnConfigurationError>
- <!--
  Controls what version of Lucene various components of Solr
  adhere to.  Generally, you want to use the latest version to
  get all bug fixes and improvements.  It is highly recommended
  that you fully re-index after changing this setting as it can
  affect both how text is indexed and queried.

```

The `solrconfig.xml` file.

Running Field Analysis to Test Analyzers, Tokenizers, and TokenFilters

When defining fields and field types, and configuring [Analyzers, Tokenizers, and TokenFilters](#), it's helpful to see how the current configuration of Solr indexes a sample text and processes a sample query. The Field Analysis feature of the Solr Admin UI makes it easy to run queries against sample text, so you can assess the current configuration of the Solr server.

Click the `ANALYSIS` link to display the Field Analysis form, shown below.

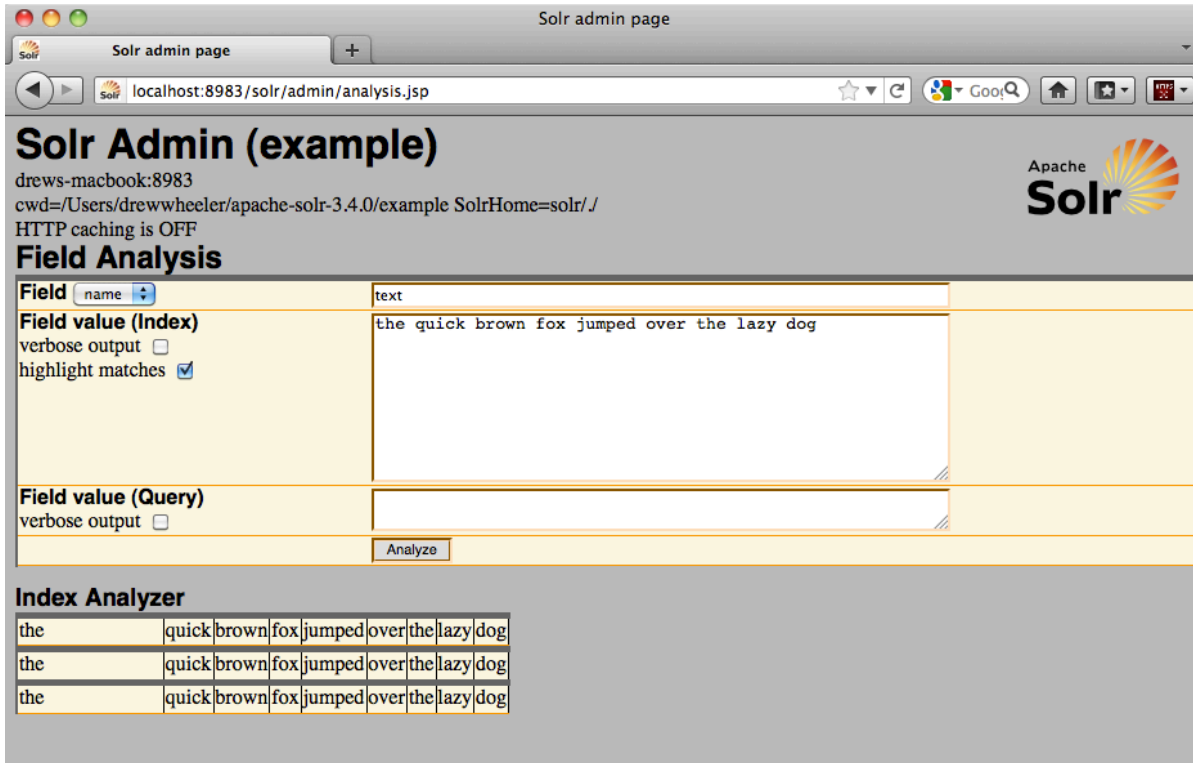

The Field Analysis form.

The Field Analysis form includes three main parts:

- A **Field name/type** field, in which you toggle a drop-down menu to select **name** or **type**, then enter the name of the field name or field type in the text box to the right. The value you enter must correspond to a field name or field type defined in the Solr server's schema.xml file.
- A **Field value (Index)** text box, in which you type sample text for a field, as though it were a field in a document indexed by Solr. To see a detailed analysis of how the Solr server calls Analyzers, Tokenizers, and TokenFilters to index the text, click the checkbox to select "verbose output."
- A **Field value (Query)** text box, in which you type the text to be used in a query performed by the Server against the text you entered in the **Field value (Index)** text box. To see details of how the Server processes the query, click the checkbox to select "verbose output."

The image below shows the Field Analysis form performing a query against text entered in the **Field value (Index)** field.

Field Analysis form performing a query against text entered in the Field value (Index) field.

To see these processes in detail, one can re-run the analysis, selecting the **verbose output** options. The following image shows the verbose output for the indexing process. You can see the order in which Tokenizers and TokenFilters are called, beginning with the WhiteSpaceTokenizerFactory, which demarcates words by identifying the white spaces around them.

Solr Admin (example)

The verbose output option for the query process.

Using the Schema Browser

The Schema Browser is a dynamic Ajax-based window for viewing details of the Solr server's schema, which defines fields, dynamic fields, and field types used for indexing. When you first open the browser, it displays three categories on the left side of the screen: fields, dynamic fields, and field types, as shown below.

The Schema Browser.

Displaying the Configuration of a Field

The Schema Browser makes it easy to explore the definitions of fields, dynamic fields, and field types. To display the Schema Browser, click the `SCHEMA BROWSER` link in the Solr Admin UI.

In the left hand navigation bar, click the word **Fields** to see a list of fields defined in the `schema.xml` file. Then click on a specific field's name to see details about that particular field.

The screenshot shows the Solr Admin interface. The browser address bar is `localhost:8983/solr/admin/schema.jsp`. The page title is "Solr Admin (example)". The user is logged in as "drews-macbook:8983". The current field selected is "text".

Field: text
Field Type: [TEXT_GENERAL](#)
Properties: Indexed, Tokenized, Multivalued
Schema: Indexed, Tokenized, Multivalued
Index: (unstored field)
Copied From: [CAT](#) [MANU](#) [NAME](#) [FEATURES](#) [INCLUDES](#)
Position Increment Gap: 100
Index Analyzer: [org.apache.solr.analysis.TokenizerChain](#) [DETAILS](#)
Query Analyzer: [org.apache.solr.analysis.TokenizerChain](#) [DETAILS](#)
Docs: 17
Distinct: 374

Top 10 Terms

term	frequency
electronics	14
inc	8
memory	5
usb	5
2.0	5
lcd	5
sdram	4
tft	4
cable	4
card	4

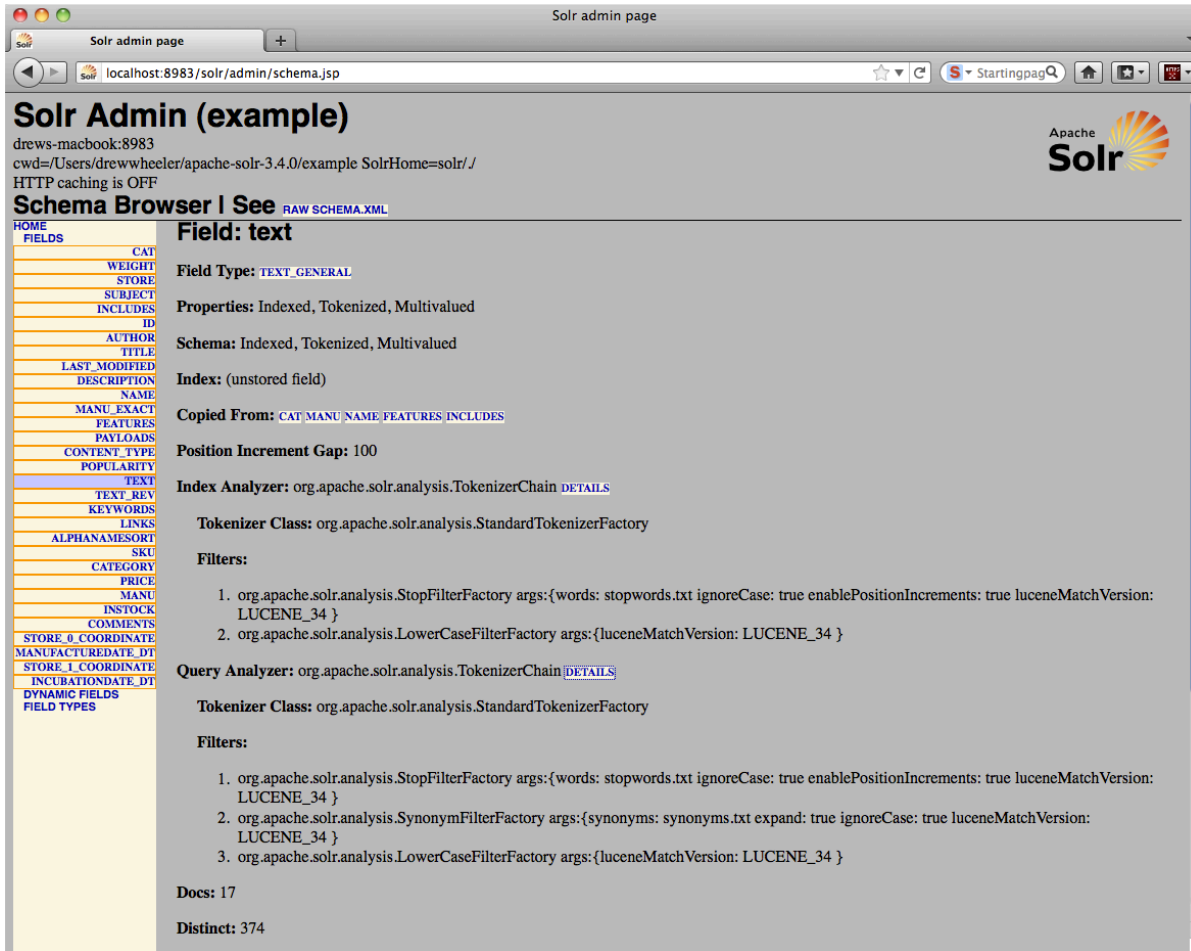

Histogram

Bin	Count
1	278
2	66
4	24
8	5
16	1

The Schema Browser displaying information about a selected field.

Displaying Additional Details about a Parameter

The schema information for some fields includes low-level details which are not displayed by default. If an item includes a `DETAILS` link, you can click the link to see additional details. To hide the additional details, click the `DETAILS` link again.

Click the *DETAILS* link to see additional details about a configuration parameter.

Exploring the Most Popular Terms for a Field

Toward the bottom of the page, the Schema Browser presents a table of terms and a bar chart related to the selected field. The table, Top *n* Terms, where *n* is by default 10, lets you see the most popular *n* terms in that field in the index. You can enter a different number for *n* in the form and see a shortened or lengthened list of terms (depending on whether you enter a lower or higher number for *n*). If you enter a number that exceeds the number of terms found in that field, the form automatically substitutes the total number of terms and displays only that number of terms. The image below shows an example of this display.

The screenshot shows the Solr Admin interface for a 'text' field. On the left is a sidebar with a list of fields including CAT, WEIGHT, STORE, SUBJECT, INCLUDES, ID, AUTHOR, TITLE, LAST_MODIFIED, DESCRIPTION, NAME, MANU_EXACT, FEATURES, PAYLOADS, CONTENT_TYPE, POPULARITY, TEXT, TEXT_REV, KEYWORDS, LINKS, ALPHANAMESORT, SKU, CATEGORY, PRICE, MANU, INSTOCK, COMMENTS, STORE_0_COORDINATE, MANUFACTUREDATE_DT, STORE_1_COORDINATE, INCUBATIONDATE_DT, DYNAMIC FIELDS, and FIELD TYPES. The main content area displays the following details for the 'text' field:

- Field Type:** TEXT_GENERAL
- Properties:** Indexed, Tokenized, Multivalued
- Schema:** Indexed, Tokenized, Multivalued
- Index:** (unstored field)
- Copied From:** CAT MANU NAME FEATURES INCLUDES
- Position Increment Gap:** 100
- Index Analyzer:** org.apache.solr.analysis.TokenizerChain [DETAILS](#)
- Query Analyzer:** org.apache.solr.analysis.TokenizerChain [DETAILS](#)
- Docs:** 17
- Distinct:** 374

Below the details is a 'Top 10 Terms' table and a 'Histogram' chart.

term	frequency
electronics	14
inc	8
memory	5
usb	5
2.0	5
lcd	5
sdram	4
tft	4
cable	4
card	4

The histogram shows the number of terms with a given frequency. The x-axis represents frequency (1, 2, 4, 8, 16) and the y-axis represents the number of terms. The bars show 278 terms with frequency 1, 66 terms with frequency 2, 24 terms with frequency 4, 5 terms with frequency 8, and 1 term with frequency 16.

Displaying the top n terms.

A histogram shows the number of terms with a given frequency in the field. For example, in the image above, there are six terms that appear once, eight terms that appear twice, and so on.

Displaying Statistics of the Solr Server

The `STATISTICS` link displays statistics related to the Solr server's performance. The server continually updates these statistics. The image below shows an example of the statistics reported by the Statistics page.

Solr Statistics: (example)

The Solr Statistics page.

The Solr Statistics page groups its data into several sections: core, cache, query, update, highlighting, and other. To jump to the reported data about a particular topic, click on that topic's link (for example, `CORE`) at the top of the Solr Statistics page.

Displaying Start-up Time Statistics about the Solr Server

To display statistics about the server at start-up time, click the INFO link. Unlike the information displayed by the STATISTICS link, the Solr information displayed by INFO is not continuously updated.

The Solr Info page reports configuration details and statistics.

Displaying Information about a Distributed Solr Configuration

Click the `DISTRIBUTION` link to see information about master and slave servers. In master/slave configurations, the master server's index is replicated on one or more slave servers, which process queries (for more information about replicated indexes, see [Scaling and Distribution](#)).

On a master server, the Admin UI's Distribution Info reports information about the snapshot of the index being distributed to slave servers.

On a master server, the Distribution Info page identifies the filename of the master server index snapshot and reports on the replication of this snapshot to any slave servers.

On a slave server, the Distribution Info page shows simply information for the slave server itself, as shown below. The page identifies which version of the replicated index the slave server is using. It also reports on the status of the most recent replication process.

Solr replication (example) Slave

[RETURN TO ADMIN PAGE](#)

The Distribution Info page for a slave server.

Pinging the Solr Server to Test Its Responsiveness

The `ping` command, which is supported by Windows, Linux, and MacOS, sends a signal to a network-accessible server and reports the time it takes the server to respond, if it responds at all. The command executable is stored at `/admin/ping` on the Solr server. The `ping` command is a straightforward, convenient tool for checking whether or not a server is running.

To run ping against the Solr server, click the `PING` link. If the server is running, the Admin UI displays an XML-formatted response like that shown below.

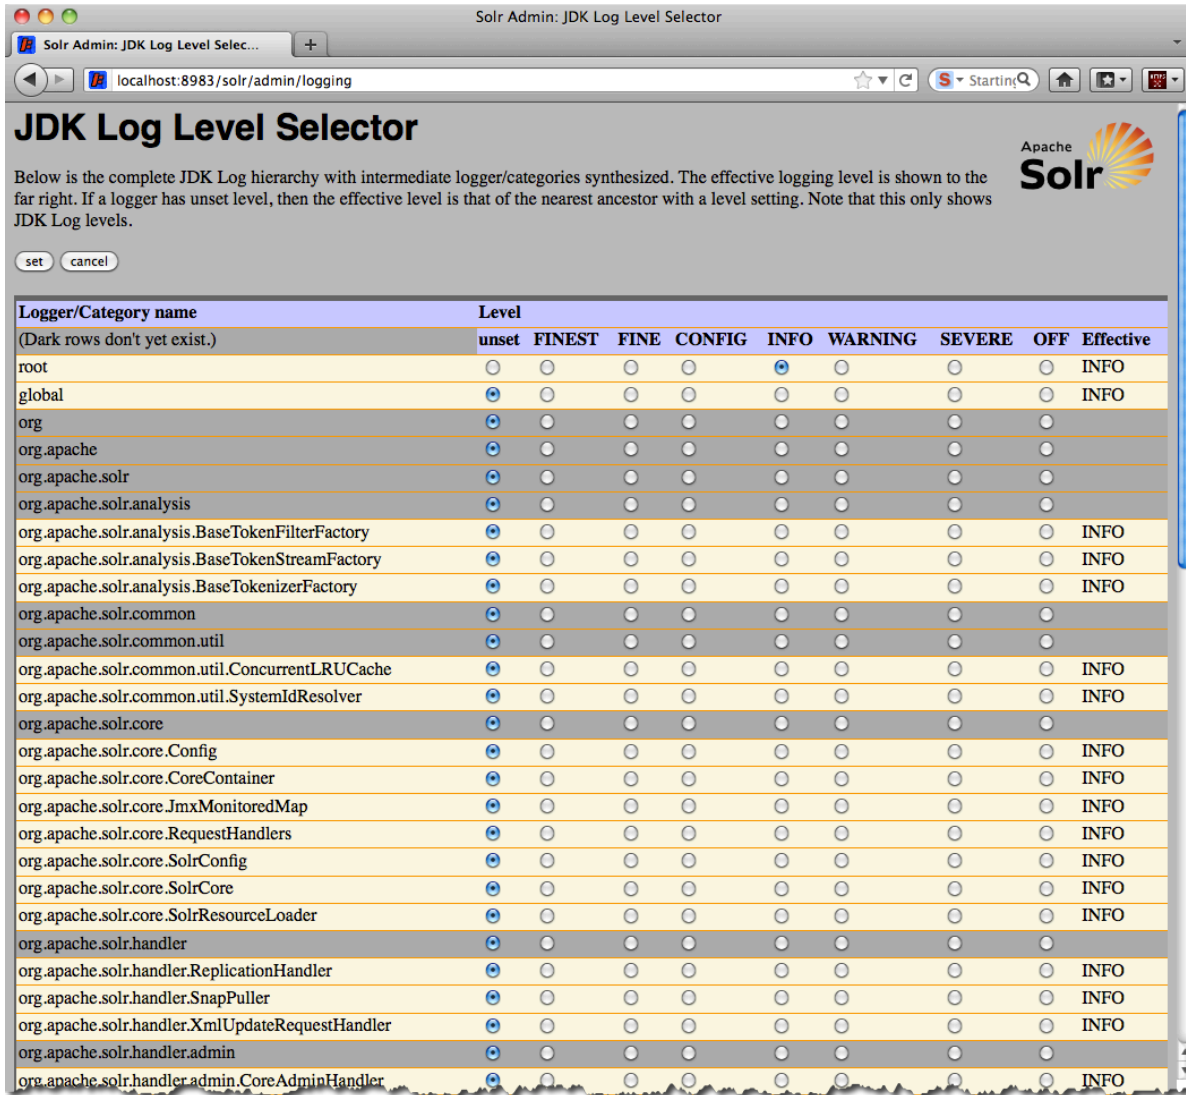

An XML-formatted response to the `ping` command.

Viewing and Configuring Logfile Settings

Click the `LOGGING` link to display a long page that offers radio-button settings for JDK logfiles.

 Any changes you make to logfile settings through Admin UI will last only as long as the current Solr session. Once the server is shut down and restarted, settings will revert to the configuration specified in the logfile configuration files.

The JDK Log Level Selector page.

The table below describes the various levels for logging used in JDK logfiles. See "An Introduction to the Java Logging API," O'Reilly Media,

<http://www.onjava.com/pub/a/onjava/2002/06/19/log.html>

Level	Usage
SEVERE	The highest value; intended for extremely important messages (such as fatal program errors).
WARNING	Intended for warning messages.
INFO	Informational run-time messages.
CONFIG	Informational messages about configuration settings.

FINE	Used for greater detail when debugging/diagnosing problems.
FINEST	The lowest value; provides the greatest detail.
ALL	All messages.
OFF	No messages.

The App Server Section

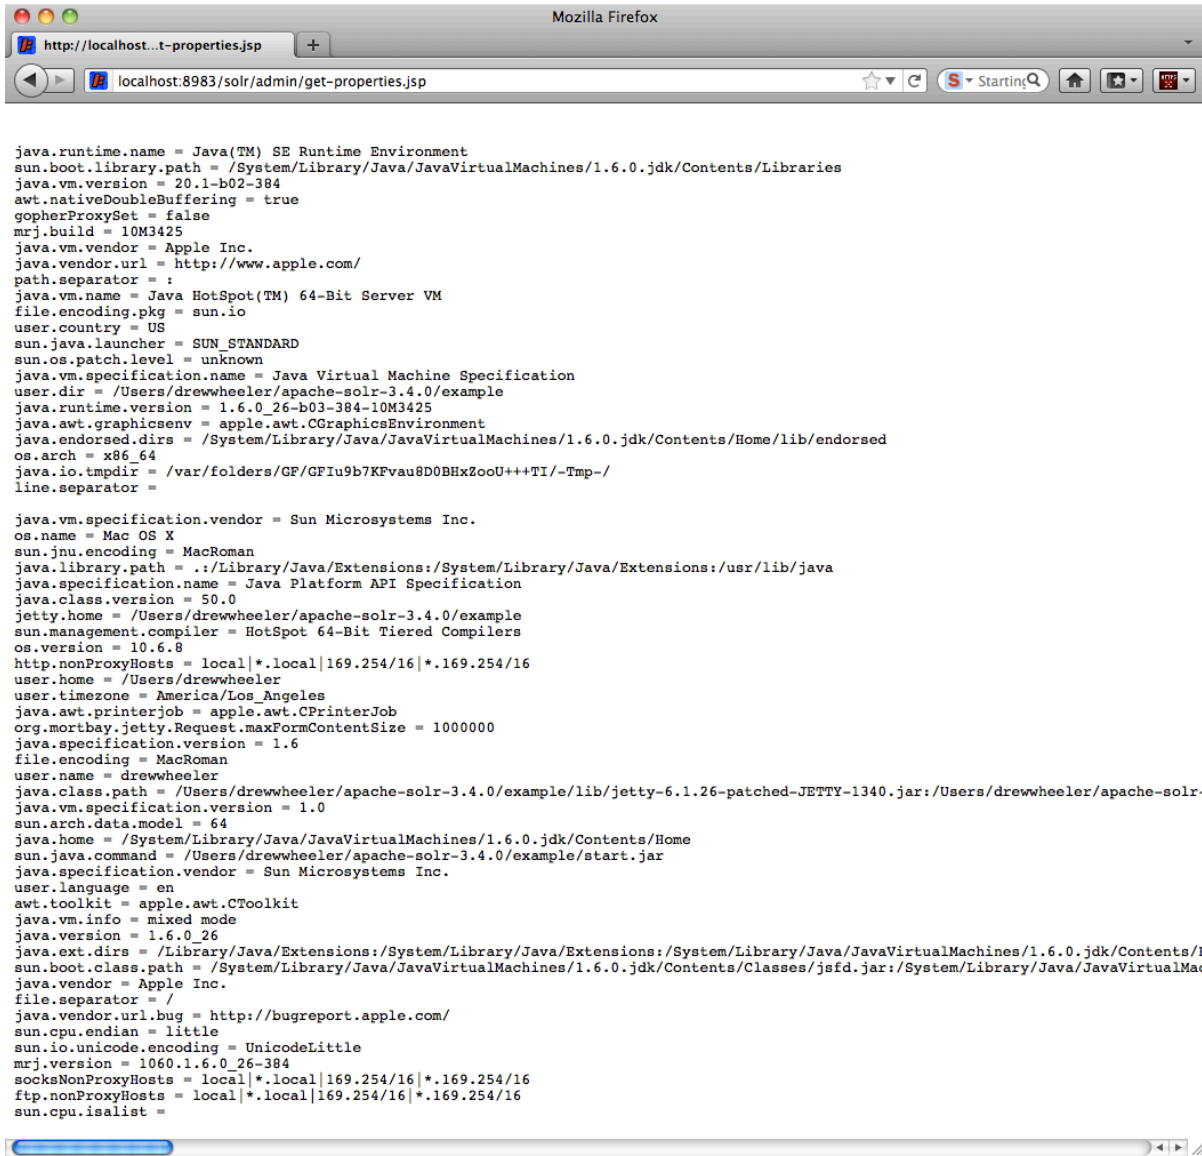

The App Server section of the Admin UI always displays a `JAVA PROPERTIES` link and a `THREAD DUMP` link. It may also display an `ENABLE/DISABLE` link, depending on the configuration of the `<admin>` block in the `solrconfig.xml` file.

The table below describes the links in the App Server section.

Link	Description
<code>JAVA PROPERTIES</code>	Displays the properties of the Solr server's Java environment.
<code>THREAD DUMP</code>	Displays a thread dump of the Solr server's Java HotSpot VM.
<code>ENABLE/DISABLE</code>	<p>Enables or disables the Solr application server by creating or removing the file specified in the optional <code><healthcheck></code> tag in the <code><admin></code> block of <code>solrconfig.xml</code>. If the <code><healthcheck></code> tag is absent, the <code>ENABLE/DISABLE</code> link does not appear in the Admin UI.</p> <p>When using load balancers, this feature makes it easy to take a server in or out of rotation by enabling or disabling the server and causing its healthcheck to succeed or fail.</p>

Displaying Java Properties

To see the properties of the Java Runtime Environment in which the Solr server is running, click the `JAVA PROPERTIES` link. The server reports Java configuration details, as shown below.

```

java.runtime.name = Java(TM) SE Runtime Environment

```

The Thread Dump display.

Enabling or Disabling the Server in a Load-balanced Configuration

This link is only displayed if a `<healthcheck>` directive appears in the `<admin>` block of the `solrconrfig.xml` file. For example:

```
<healthcheck type="file">solr/conf/healthcheck.txt</healthcheck>
```

When using load balancers, the `ENABLE/DISABLE` link makes it easy to take a server in or out of rotation by making a healthcheck succeed or fail.

Clicking `ENABLE/DISABLE` changes the contents of the healthcheck file:

<http://localhost:8983/solr/admin/file/?file=healthcheck.txt>

Changing the file toggles the function of the server, either enabling or disabling it for rotation with the load balancer.

The Make a Query Section

You can use the **Make a Query** section of the Admin UI to submit a search query to the Solr server and analyze the results. The server returns the query results to the browser as XML, as shown in the following screen shot:

```

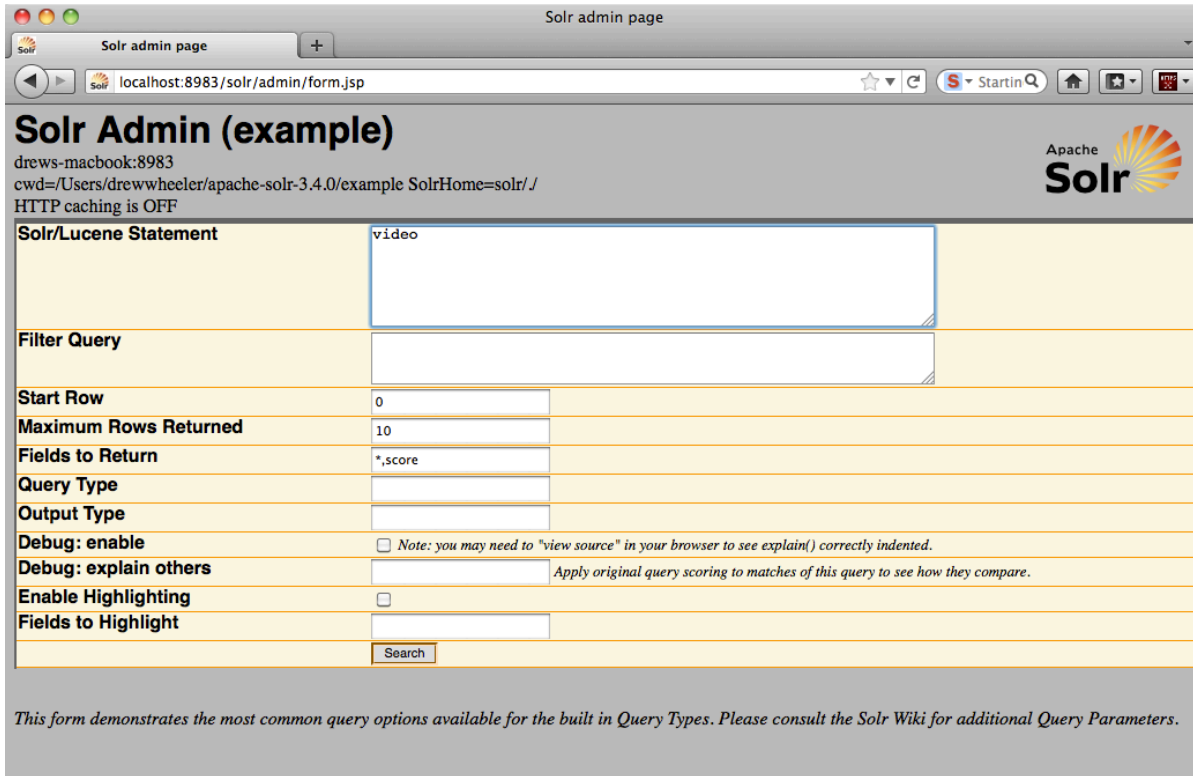

- <response>
  - <lst name="responseHeader">
    <int name="status">0</int>
    <int name="QTime">0</int>
  - <lst name="params">
    <str name="q">video</str>
  </lst>
- <result name="response" numFound="3" start="0">

```

Query results are displayed in XML.

Using the Full Interface to Submit Queries

For more control over the details of the query and its response, click the `FULL INTERFACE` link. The Solr server displays a new page like that shown below.

The Full Search query interface.

The table below explains the fields in this form:

Field	Description
Solr/Lucene Statement	The Lucene/Solr query to be submitted. For a description of query syntax, see Searching .
Start Row	The offset into the query result starting at which documents should be returned. The default value is 0, meaning that the query should return results starting with the first document that matches. This field accepts the same syntax as the start query parameter, which is described in Searching
Maximum Rows Returned	The number of rows of results that should be displayed at one time for pagination. The default is 10. Accepts the same syntax as the rows query parameter.
Fields to Return	Specifies a list of fields to return. Accepts the same syntax as the fl query parameter.
Query Type	Specifies the query handler for the request. If a query handler is not specified, Solr processes the query with the standard query handler.

Response Type	Specifies a response handler for the request. If a response handler is not specified, Solr processes the response with the standard response handler.
Debug: enable	Augments the query response with debugging information, including "explain info" for each document returned. This debugging information is intended to be intelligible to the administrator or programmer.
Debug: explain others	Accepts a Lucene query identifying a set of documents. If non-blank, the "explain info" data of each document matching this query, relative the main query (specified in the Solr/Lucene Statement field) will be returned along with the rest of the debugging information.
Enable Highlighting	Causes the query response to highlight the fields specified in the Fields to Highlight box in the form.
Fields to Highlight	Specifies which fields in the response to highlight, if highlighting is enabled.

The Assistance Section

The Assistance section includes the following links.

Link	Description

Documents, Fields, and Schema Design

This section discusses how Solr organizes its data into documents and field, as well as how to work with the Solr schema file, `schema.xml`. It includes the following topics:

[Overview of Documents, Fields, and Schema Design](#): An introduction to the concepts covered in this section.

[Solr Field Types](#): Detailed information about field types in Solr, including the field types in the default Solr schema.

[Defining Fields](#): Describes how to define fields in Solr.

[Copying Fields](#): Describes how to copy fields in Solr.

[Dynamic Fields](#): Information about using dynamic fields in Solr in order to catch and index fields that do not exactly conform to other field definitions in your schema.

[Other Schema Elements](#): Describes other important elements in the Solr schema: Unique Key, Default Search Field, and the Query Parser Operator.

[Putting the Pieces Together](#): A higher-level view of the Solr schema and how its elements work together.

Overview of Documents, Fields, and Schema Design

The fundamental premise of Solr is simple. You feed it a lot of information, then later you can ask it questions and find the piece of information you want. The part where you feed in all the information is called *indexing* or *updating*. When you ask a question, it's called a *query*.

One way to understand how Solr works is to think of a loose-leaf book of recipes. Every time you add a recipe to the book, you update the index at the back. You list each ingredient and the page number of the recipe you just added. Suppose you add one hundred recipes. Using the index, you can very quickly find all the recipes that use garbanzo beans, or artichokes, or coffee, as an ingredient. Using the index is much faster than looking through each recipe one by one. Imagine a book of one thousand recipes, or one million.

Solr allows you to build an index with many different fields, or types of entries. The example above shows how to build an index with just one field, *ingredients*. You could have other fields in the index for the recipe's cooking style, like *Asian*, *Cajun*, or *vegan*, and you could have an index field for preparation times. Solr can answer questions like "What Cajun-style recipes that have blood oranges as an ingredient can be prepared in fewer than 30 minutes?"

The schema is the place where you tell Solr how it should build indexes from input documents.

How Solr Sees the World

Solr's basic unit of information is a *document*, which is a set of data that describes something. A recipe document would contain the ingredients, the instructions, the preparation time, the cooking time, the tools needed, and so on. A document about a person, for example, might contain the person's name, biography, favorite color, and shoe size. A document about a book could contain the title, author, year of publication, number of pages, and so on.

In the Solr universe, documents are composed of *fields*, which are more specific pieces of information. Shoe size could be a field. First name and last name could be fields.

Fields can contain different kinds of data. A name field, for example, is text (character data). A shoe size field might be a floating point number so that it could contain values like 6 and 9.5. Obviously, the definition of fields is flexible (you could define a shoe size field as a text field rather than a floating point number, for example), but if you define your fields correctly, Solr will be able to interpret them correctly and your users will get better results when they perform a query.

You can tell Solr about the kind of data a field contains by specifying its *field type*. The field type tells Solr how to interpret the field and how it can be queried.

When you add a document, Solr takes the information in the document's fields and adds that information to an index. When you perform a query, Solr can quickly consult the index and return the matching documents.

Field Analysis

Field analysis tells Solr what to do with incoming data when building an index. A more accurate name for this process would be *processing* or even *digestion*, but the official name is *analysis*.

Consider, for example, a biography field in a person document. Every word of the biography must be indexed so that you can quickly find people whose lives have had anything to do with ketchup, or dragonflies, or cryptography.

However, a biography will likely contains lots of words you don't care about and don't want clogging up your index—words like "the," "a," "to," and so forth. Furthermore, suppose the biography contains the word "Ketchup," capitalized at the beginning of a sentence. If a user makes a query for "ketchup," you want Solr to tell you about the person even though the biography contains the capitalized word.

The solution to both these problems is field analysis. For the biography field, you can tell Solr how to break apart the biography into words. You can tell Solr that you want to make all the words lower case, and you can tell Solr to remove accents marks.

Field analysis is an important part of a field type. [Understanding Analyzers, Tokenizers, and Filters](#) is a detailed description of field analysis.

Solr Field Types

The field type defines how Solr should interpret data in a field and how the field can be queried. There are many field types included with Solr by default, and they can be defined locally also.

Topics covered in this section:

- [Field Type Definitions in `schema.xml`](#)
- [Field Types Included with Solr](#)
- [Working with Dates](#)
- [Working with External Files](#)
- [Field Type Properties](#)
- [Field Properties by Use Case](#)

Field Type Definitions in `schema.xml`

A field type includes four types of information:

- The name of the field type
- An implementation class name
- If the field type is `TextField`, a description of the field analysis for the field type
- Field attributes

In `schema.xml`, the field types are defined in the `types` element. Here is an example of a field type definition:

```
<fieldType name="textTight" class="solr.TextField"
  positionIncrementGap="100" >
  <analyzer>
    <tokenizer class="solr.WhitespaceTokenizerFactory"/>
    <filter class="solr.SynonymFilterFactory"
      synonyms="synonyms.txt" ignoreCase="true" expand="false"/>
    <filter class="solr.WordDelimiterFilterFactory"
      generateWordParts="0" generateNumberParts="0"
      catenateWords="1" catenateNumbers="1" catenateAll="0"/>
    <filter class="solr.LowerCaseFilterFactory"/>
    <filter class="solr.SnowballPorterFilterFactory"
      language="English" protected="protwords.txt"/>
    <filter class="solr.RemoveDuplicatesTokenFilterFactory"/>
  </analyzer>
</fieldType>
```

The first line in the example above contains the field type name, `textTight`, and the name of the implementing class, `solr.TextField`. The rest of the definition is about field analysis, described in [Understanding Analyzers, Tokenizers, and Filters](#).

The implementing class is responsible for making sure the field is handled correctly. In the class names in `schema.xml`, the string `solr` is shorthand for `org.apache.solr.schema` or `org.apache.solr.analysis`. Therefore, `solr.TextField` is really `org.apache.solr.schema.TextField`.

Field Types Included with Solr

The following table lists the field types that are available in Solr 3.4. The `org.apache.solr.schema` package includes all the classes listed in this table.

Class	Description
<code>BCDIntField</code>	Binary-coded decimal (BCD) integer. BCD is a relatively inefficient encoding that offers the benefits of quick decimal calculations and quick conversion to a string.
<code>BCDLongField</code>	BCD long integer
<code>BCDStrField</code>	BCD string
<code>BinaryField</code>	Binary data
<code>BoolField</code>	Contains either true or false. Values of "1", "t", or "T" in the first character are interpreted as true. Any other values in the first character are interpreted as false.
<code>ByteField</code>	Contains an array of bytes.
<code>DateField</code>	Represents a point in time with millisecond precision. See the section below.
<code>DoubleField</code>	Double
<code>ExternalFileField</code>	Pulls values from a file on disk. See the section below on working with external files.
<code>FloatField</code>	Floating point
<code>IntField</code>	Integer
<code>Location</code>	For spatial search: a latitude/longitude coordinate pair.
<code>LongField</code>	Long integer
<code>Point</code>	For spatial search: An arbitrary n-dimensional point, useful for searching sources such as blueprints or CAD drawings.

RandomSortField	Does not contain a value. Queries that sort on this field type will return results in random order. Use a dynamic field to use this feature.
ShortField	Short integer
SortableDoubleField	The Sortable* fields provide correct numeric sorting. If you use the plain types (DoubleField, IntField, and so on) sorting will be lexicographical instead of numeric.
SortableFloatField	Numerically sorted floating point
SortableIntField	Numerically sorted integer
SortableLongField	Numerically sorted long integer
StrField	String
TextField	Text, usually multiple words or tokens
TrieDateField	Date field accessible for Lucene TrieRange processing
TrieDoubleField	Double field accessible Lucene TrieRange processing
TrieField	If this type is used, a "type" attribute must also be specified, with a value of either: integer, long, float, double, date. Using this field is the same as using any of the Trie*Fields.
TrieFloatField	Floating point field accessible Lucene TrieRange processing
TrieIntField	Int field accessible Lucene TrieRange processing
TrieLongField	Long field accessible Lucene TrieRange processing
UUIDField	Universally Unique Identifier (UUID). Pass in a value of "NEW" and Solr will create a new UUID.

Working with Dates

DateField represents a point in time with millisecond precision. The format is:

YYYY-MM-DDThh:mm:ssZ

YYYY is the year.

MM is the month.

DD is the day of the month.

hh is the hour of the day as on a 24-hour clock.

mm is minutes.

ss is seconds.

Note that no time zone can be specified; the time given should be expressed in Coordinated Universal Time (UTC). Here is an example value:

```
1972-05-20T17:33:18Z
```

You can include fractional seconds if you wish, although trailing zeros are not allowed and any precision beyond milliseconds will be ignored. Here is another example value with milliseconds included:

```
1972-05-20T17:33:18.772Z
```

In addition, `DateField` also supports *date math*. This makes it easy to create times relative to the current time. This represents a point in time two months from now:

```
+2MONTHS
```

This is one day ago:

```
-1DAY
```

Use a slash to indicate rounding. This represents the beginning of the current hour:

```
/HOUR
```

You can combine terms. The following is six months and three days in the future, at the beginning of the day:

```
+6MONTHS+3DAYS/DAY
```

Working with External Files

`ExternalFileField` makes it possible to specify field values for documents in a file. For such a field, the file contains mappings from a key field to the field value. Another way to think of this is that, instead of specifying the field in documents as they are indexed, Solr finds values of this field in the external file.

External fields are not searchable. They can be used only for function queries. For more information on function queries, see [Searching](#).

`ExternalFileField` is handy for cases where you want to update a particular field in many documents more often than you want to update the rest of the documents. For example, suppose you have some kind of document rank based on number of views. You might want to update the rank of all the documents daily or hourly, while the rest of the contents of the documents might be updated much less frequently.

Without `ExternalFileField`, you would need to update each document just to change the rank. Using `ExternalFileField` is much more efficient because all document values for a particular field are stored in an external file that can be updated as frequently as you wish.

An attribute in the field type declaration, `valType`, specifies the actual type of the values that will be found in the file. Note that only float fields are currently supported (`FloatField` type or a subclass).

```
<fieldType name="entryRankFile" keyField="pkId" defVal="0"
  stored="false" indexed="false"
  class="solr.ExternalFileField" valType="float"/>
```

The file itself is located in Solr's index directory, which by default is `data/index` in the Solr home directory. The name of the file should be `_external_<fieldname>` or `_external_<fieldname>.*`. For the example above, then, the file could be named `_external_entryRankFile` or `_external_entryRankFile.txt`.

 If any files using the name pattern `.*` appear, the last (after being sorted by name) will be used and previous versions will be deleted. This behavior supports implementations on systems where one may not be able to overwrite a file (for example, on Windows, if the file is in use).

The file contains entries that map a key field, on the left of the equals sign, to a value, on the right. Here are a few example entries:

```
doc33=1.414
doc34=3.14159
doc40=42
```

Field Type Properties

The field type class determines most of the behavior of a field type, but optional properties can also be defined in `schema.xml`. For example, the following definition of a date field type defines two properties, `sortMissingLast` and `omitNorms`.

```
<fieldType name="date" class="solr.DateField"
  sortMissingLast="true" omitNorms="true"/>
```

Most properties are either true or false.

Here are some commonly used properties:

Field Property	Description	Values
indexed	If true, the value of the field can be used in queries to retrieve matching documents	true or false
stored	If true, the actual value of the field can be retrieved by queries	true or false
sortMissingFirst sortMissingLast	Control the placement of documents when a sort field is not present	true or false
multiValued	If true, indicates that a single document might contain multiple values for this field type	true or false
positionIncrementGap	For multivalued fields, specifies a distance between multiple values, which prevents spurious phrase matches	integer
omitNorms	If true, omits the norms associated with this field (this disables length normalization and index-time boosting for the field, and saves some memory). Only full-text fields or fields that need an index-time boost need norms.	true or false
omitTermFreqAndPositions	If true, omits term frequency, positions, and payloads from postings for this field. This can be a performance boost for fields that don't require that information. It also reduces the storage space required for the index. Queries that rely on position that are issued on a field with this option will silently fail to find documents. This property defaults to true for all fields that are not text fields.	true or false
autoGeneratePhraseQueries	For text fields. If true, Solr automatically generates phrase queries for adjacent terms. If false, terms must be enclosed in double-quotes to be treated as phrases.	

Field Properties by Use Case

Here is a summary of available options on a field, broken down by use case. A true or false indicates that the option must be set to the given value for the use case to function correctly.

Use Case	indexed	stored	multiValued	omitNorms	termVectors	termPositions
search within field	true					
retrieve contents		true				

use as unique key	true		false			
sort on field	true		false	true [1]		
use field boosts [5]				false		
document boosts affect searches within field				false		
highlighting	true [4]	true			[2]	true [3]
faceting [5]	true					
add multiple values, maintaining order			true			
field length affects doc score				false		
MoreLikeThis [5]					true [6]	

Notes:

- 1: Recommended but not necessary.
- 2: Will be used if present, but not necessary .
- 3: (if termVectors=true)
- 4: A tokenizer must be defined for the field, but it doesn't need to be indexed.
- 5: Described in [Understanding Analyzers, Tokenizers, and Filters](#).
- 6: Term vectors are not mandatory here. If not true, then a stored field is analyzed. So term vectors are recommended, but only required if stored=false.

Defining Fields

Once you have the field types set up just the way you like, defining the fields themselves is simple. All you do is supply a name and a field type. If you wish, you can also provide options that will override the options for the field type.

Fields are defined in the `fields` element of `schema.xml`. The following example defines a field named `price` with a type of `sfloat`.

```
<field name="price" type="sfloat" indexed="true" stored="true"/>
```

Fields can have the same options as field types. The field type options serve as defaults which can be overridden by options defined per field.

Copying Fields

You might want to interpret some document fields in more than one way. Solr has a mechanism for making copies of fields so that you can apply several distinct field types to a single piece of incoming information. For Linux shell geeks, this is something like `tee`.

The name of the field you want to copy is the *source*, and the name of the copy is the *destination*. In `schema.xml`, it's very simple to make copies of fields:

```
<copyField source="cat" dest="text" maxChars="30000" />
```

If the text field has data of its own in input documents, the contents of `cat` will be added to the index for `text`. The `maxChars` parameter, an `int` parameter, establishes an upper limit for the number of characters to be copied. This limit is useful for situations in which you want to control the size of index files.

Both the source and the destination of `copyField` can contain asterisks, which will match anything. For example, the following line will copy the contents of all incoming fields that match the wildcard pattern `*t` to the text field.:

```
<copyField source="*_t" dest="text" maxChars="25000" />
```

 The `copyField` command can use a wildcard (*) character in the `dest` parameter only if the source parameter contains one as well. `copyField` uses the matching glob from the source field for the `dest` field name into which the source content is copied.

Dynamic Fields

Dynamic fields allow Solr to index fields that you did not explicitly define in your schema. This is useful if you discover you have forgotten to define one or more fields. Dynamic fields can make your application less brittle by providing some flexibility in the documents you can add to Solr.

A dynamic field is just like a regular field except it has a name with a wildcard in it. When you are indexing documents, a field that does not match any explicitly defined fields can be matched with a dynamic field.

For example, suppose your schema includes a dynamic field with a name of `*_i`. If you attempt to index a document with a `cost_i` field, but no explicit `cost_i` field is defined in the schema, then the `cost_i` field will have the field type and analysis defined for `*_i`.

Dynamic fields are also defined in the `fields` element of `schema.xml`. Like fields, they have a name, a field type, and options.

```
<dynamicField name="*_i" type="sint" indexed="true" stored="true"/>
```

Lucid Imagination recommends that you include basic dynamic field mappings (like that shown above) in your `schema.xml`. The mappings can be very useful.

Other Schema Elements

This section describes several other important elements of `schema.xml`.

Unique Key

The `uniqueKey` element specifies which field is a unique identifier for documents. Although `uniqueKey` is not required, it is nearly always warranted by your application design. For example, `uniqueKey` should be used if you will ever update a document in the index. For more information, consult the Solr Wiki at <http://wiki.apache.org/solr/UniqueKey>.

You can define the unique key field by naming it:

```
<uniqueKey>id</uniqueKey>
```

Default Search Field

If you are using the Lucene query parser, queries that don't specify a field name will use the `defaultSearchField`. The DisMax and Extended DisMax query parsers do not use this value. For more information about query parsers, see [Searching](#).

Just name a field to use it as the default search field:

```
<defaultSearchField>text</defaultSearchField>
```

Query Parser Operator

In queries with multiple terms, Solr can either return results where all conditions are met or where one or more conditions are met. The *operator* controls this behavior. An operator of AND means that all conditions must be fulfilled, while an operator of OR means that one or more conditions must be true.

In `schema.xml`, use the `solrQueryParser` element to control what operator is used if an operator is not specified in the query. The default operator setting only applies to the Lucene query parser, not the DisMax or Extended DisMax query parsers, which internally hard-code their operators to OR.

```
<solrQueryParser defaultOperator="OR"/>
```

Putting the Pieces Together

At the highest level, `schema.xml` is structured as follows. This example is not real XML, but it gives you an idea of the important parts of the file.

```
<schema>
  <types>
  <fields>
  <uniqueKey>
  <defaultSearchField>
  <solrQueryParser defaultOperator>
  <copyField>
</schema>
```

Obviously, most of the excitement is in types and fields, where the field types and the actual field definitions live. These are supplemented by `copyFields`. Sandwiched between fields and the `copyField` section are the unique key, default search field, and the default query operator.

For more information about `schema.xml`, see <http://wiki.apache.org/solr/SchemaXml>.

Choosing Appropriate Numeric Types

For general numeric needs, use the sortable field types, `SortableIntField`, `SortableLongField`, `SortableFloatField`, and `SortableDoubleField`. These field types will sort numerically instead of lexicographically, which is the main reason they are preferable over their simpler cousins, `IntField`, `LongField`, `FloatField`, and `DoubleField`.

If you expect users to make frequent range queries on numeric types, consider using `TrieField`. It offers faster speed for range queries at the expense of increasing index size.

Working With Text

Handling text properly will make your users happy by providing them with the best possible results for text searches.

One technique is using a text field as a catch-all for keyword searching. Most users are not sophisticated about their searches and the most common search is likely to be a simple keyword search. You can use `copyField` to take a variety of fields and funnel them all into a single text field for keyword searches. In the example schema representing a store, `copyField` is used to dump the contents of `cat`, `name`, `manu`, `features`, and `includes` into a single field, `text`. In addition, it could be a good idea to copy `ID` into `text` in case users wanted to search for a particular product by passing its product number to a keyword search.

Another technique is using `copyField` to use the same field in different ways. Suppose you have a field that is a list of authors, like this:

```
Schildt, Herbert; Wolpert, Lewis; Davies, P.
```

For searching by author, you could tokenize the field, convert to lower case, and strip out punctuation:

```
schildt / herbert / wolpert / lewis / davies / p
```

For sorting, just use an untokenized field, converted to lower case, with punctuation stripped:

```
schildt herbert wolpert lewis davies p
```

Finally, for faceting, use the primary author only via a `StringField`:

```
Schildt, Herbert
```

Understanding Analyzers, Tokenizers, and Filters

This sections describes how Solr breaks down and works with textual data. It covers the following topics:

[Overview of Analyzers, Tokenizers, and Filters](#): A conceptual introduction to Solr's analyzers, tokenizers, and filters.

[What Is An Analyzer?](#): Detailed conceptual information about Solr analyzers.

[What Is A Tokenizer?](#): Detailed conceptual information about Solr tokenizers.

[What Is a Filter?](#): Detailed conceptual information about Solr filters.

[Tokenizers](#): Information about configuring tokenizers, and about the tokenizer factory classes included in this distribution of Solr.

[Filter Descriptions](#): Information about configuring filters, and about the filter factory classes included in this distribution of Solr.

[CharFilterFactories](#): Information about filters for pre-processing input characters.

[Language Analysis](#): Information about tokenizers and filters for character set conversion or for use with specific languages.

[Running Your Analyzer](#): Detailed information about testing and running your Solr analyzer.

Overview of Analyzers, Tokenizers, and Filters

Field analyzers are used both during ingestion, when a document is indexed, and at query time. An analyzer examines the text of fields and generates a token stream. Analyzers may be a single class or they may be composed of a series of tokenizer and filter classes.

Tokenizers break field data into lexical units, or *tokens*. **Filters** examine a stream of tokens and keep them, transform or discard them, or create new ones. Tokenizers and filters may be combined to form pipelines, or *chains*, where the output of one is input to the next. Such a sequence of tokenizers and filters is called an *analyzer* and the resulting output of an analyzer is used to match query results or build indices.

Although the analysis process is used for both indexing and querying, the same analysis process need not be used for both operations. For indexing, you often want to simplify, or normalize, words. For example, setting all letters to lowercase, eliminating punctuation and accents, mapping words to their stems, and so on. Doing so can increase recall because, for example, "ram", "Ram" and "RAM" would all match a query for "ram". To increase query-time precision, a filter could be employed to narrow the matches by, for example, ignoring all-cap acronyms if you're interested in male sheep, but not Random Access Memory.

The tokens output by the analysis process define the values, or *terms*, of that field and are used either to build an index of those terms when a new document is added, or to identify which documents contain the terms your are querying for.

This section will show you how to configure field analyzers and also serves as a reference for the details of configuring each of the available tokenizer and filter classes. It also serves as a guide so that you can configure your own analysis classes if you have special needs that cannot be met with the included filters or tokenizers.

For more information on Solr's analyzers, tokenizers, and filters, see <http://wiki.apache.org/solr/AnalyzersTokenizersTokenFilters>.

What Is An Analyzer?

An analyzer examines the text of fields and generates a token stream. Analyzers are specified as a child of the `<fieldType>` element in the `schema.xml` configuration file that can be found in the `solr/conf` directory, or wherever `solrconfig.xml` is located.

In normal usage, only fields of type `solr.TextField` will specify an analyzer. The simplest way to configure an analyzer is with a single `<analyzer>` element whose class attribute is a fully qualified Java class name. The named class must derive from `org.apache.lucene.analysis.Analyzer`. For example:

```
<fieldType name="nametext" class="solr.TextField">
  <analyzer class="org.apache.lucene.analysis.WhitespaceAnalyzer"/>
</fieldType>
```

In this case a single class, `WhitespaceAnalyzer`, is responsible for analyzing the content of the named text field and emitting the corresponding tokens. For simple cases, such as plain English prose, a single analyzer class like this may be sufficient. But it's often necessary to do more complex analysis of the field content.

Even the most complex analysis requirements can usually be decomposed into a series of discrete, relatively simple processing steps. As you will soon discover in Sections and , the Solr distribution comes with a large selection of tokenizers and filters that covers most scenarios you are likely to encounter. Setting up an analyzer chain is very straightforward; you specify a simple `<analyzer>` element (no class attribute) with child elements that name factory classes for the tokenizer and filters to use, in the order you want them to run.

For example:

```
<fieldType name="nametext" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.StandardFilterFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
    <filter class="solr.StopFilterFactory"/>
    <filter class="solr.EnglishPorterFilterFactory"/>
  </analyzer>
</fieldType>
```

Note that classes in the `org.apache.solr.analysis` package may be referred to here with the shorthand `solr.` prefix.

In this case, no Analyzer class was specified on the `<analyzer>` element. Rather, a sequence of more specialized classes are wired together and collectively act as the Analyzer for the field. The text of the field is passed to the first item in the list (`solr.StandardTokenizerFactory`), and the tokens that emerge from the last one (`solr.EnglishPorterFilterFactory`) are the terms that are used for indexing or querying any fields that use the "nametext" fieldType.

Analysis Phases

Analysis takes place in two contexts. At index time, when a field is being created, the token stream that results from analysis is added to an index and defines the set of terms (including positions, sizes, and so on) for the field. At query time, the values being searched for are analyzed and the terms that result are matched against those that are stored in the field's index.

In many cases, the same analysis should be applied to both phases. This is desirable when you want to query for exact string matches, possibly with case-insensitivity, for example. In other cases, you may want to apply slightly different analysis steps during indexing than those used at query time.

If you provide a simple `<analyzer>` definition for a field type, as in the examples above, then it will be used for both indexing and queries. If you want distinct analyzers for each phase, you may include two `<analyzer>` definitions distinguished with a type attribute. For example:

```
<fieldType name="nametext" class="solr.TextField">
  <analyzer *type="index" {*>
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
    <filter class="solr.KeepWordFilterFactory" words="keepwords.txt"/>
    <filter class="solr.SynonymFilterFactory" synonyms="syns.txt"/>
  </analyzer>
  <analyzer *type="query" {*>
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
  </analyzer>
</fieldType>
```

In this theoretical example, at index time the text is tokenized, the tokens are set to lowercase, any that are not listed in `keepwords.txt` are discarded and those that remain are mapped to alternate values as defined by the synonym rules in the file `syns.txt`. This essentially builds an index from a restricted set of possible values and then normalizes them to values that may not even occur in the original text.

At query time, the only normalization that happens is to convert the query terms to lowercase. The filtering and mapping steps that occur at index time are not applied to the query terms. Queries must then, in this example, be very precise, using only the normalized terms that were stored at index time.

What Is A Tokenizer?

The job of a [tokenizer](#) is to break up a stream of text into tokens, where each token is (usually) a sub-sequence of the characters in the text. An analyzer is aware of the field it is configured for, but a tokenizer is not. Tokenizers read from a character stream (a Reader) and produce a sequence of Token objects (a TokenStream).

Characters in the input stream may be discarded, such as whitespace or other delimiters. They may also be added to or replaced, such as mapping aliases or abbreviations to normalized forms. A token contains various metadata in addition to its text value, such as the location at which the token occurs in the field. Because a tokenizer may produce tokens that diverge from the input text, you should not assume that the text of the token is the same text that occurs in the field, or that its length is the same as the original text. It's also possible for more than one token to have the same position or refer to the same offset in the original text. Keep this in mind if you use token metadata for things like highlighting search results in the field text.

```
<fieldType name="text" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.StandardTokenizerFactory"/>
  </analyzer>
</fieldType>
```

The class named in the `<tokenizer>` element is not the actual tokenizer, but rather a class that implements the `org.apache.solr.analysis.TokenizerFactory` interface. This factory class will be called upon to create new tokenizer instances as needed. Objects created by the factory must derive from `org.apache.lucene.analysis.TokenStream`, which indicates that they produce sequences of tokens. If the tokenizer produces tokens that are usable as-is, it may be the only component of the analyzer. Otherwise, the tokenizer's output tokens will serve as input to the first filter stage in the pipeline.

What Is a Filter?

Like [tokenizers](#), [filters](#) consume input and produce a stream of tokens. Filters also derive from `org.apache.lucene.analysis.TokenStream`. Unlike tokenizers, a filter's input is another `TokenStream`. The job of a filter is usually easier than that of a tokenizer since in most cases a filter looks at each token in the stream sequentially and decides whether to pass it along, replace it or discard it.

A filter may also do more complex analysis by looking ahead to consider multiple tokens at once, although this is less common. One hypothetical use for such a filter might be to normalize state names that would be tokenized as two words. For example, the single token "california" would be replaced with "CA", while the token pair "rhode" followed by "island" would become the single token "RI".

Because filters consume one `TokenStream` and produce a new `TokenStream`, they can be chained one after another indefinitely. Each filter in the chain in turn processes the tokens produced by its predecessor. The order in which you specify the filters is therefore significant. Typically, the most general filtering is done first, and later filtering stages are more specialized.

```
<fieldType name="text" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.StandardFilterFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
    <filter class="solr.EnglishPorterFilterFactory"/>
  </analyzer>
</fieldType>
```

This example starts with Solr's standard tokenizer, which breaks the field's text into tokens. Those tokens then pass through Solr's standard filter, which removes dots from acronyms, and performs a few other common operations. All the tokens are then set to lowercase, which will facilitate case-insensitive matching at query time.

The last filter in the above example is a stemmer filter that uses the Porter stemming algorithm. A stemmer is basically a set of mapping rules that maps the various forms of a word back to the base, or *stem*, word from which they derive. For example, in English the words "hugs", "hugging" and "hugged" are all forms of the stem word "hug". The stemmer will replace all of these terms with "hug", which is what will be indexed. This means that a query for "hug" will match the term "hugged", but not "huge".

Conversely, applying a stemmer to your query terms will allow queries containing non stem terms, like "hugging", to match documents with different variations of the same stem word, such as "hugged". This works because both the indexer and the query will map to the same stem ("hug").

Word stemming is, obviously, very language specific. Solr includes several language-specific stemmers created by the [Snowball](#) generator that are based on the Porter stemming algorithm. The generic Snowball Porter Stemmer Filter can be used to configure any of these language stemmers. Solr also includes a convenience wrapper for the English Snowball stemmer. There are also several purpose-built stemmers for non-English languages. These stemmers are described in [Language Analysis](#).

Tokenizers

You configure the tokenizer for a text field type in `schema.xml` with a `<tokenizer>` element, as a child of `<analyzer>`:

```
<fieldType name="text" class="solr.TextField">
  <analyzer type="index">
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.StandardFilterFactory"/>
  </analyzer>
</fieldType>
```

The class attribute names a factory class that will instantiate a tokenizer object when needed. Tokenizer factory classes implement the `org.apache.solr.analysis.TokenizerFactory`. A `TokenizerFactory`'s `create()` method accepts a `Reader` and returns a `TokenStream`. When Solr creates the tokenizer it passes a `Reader` object that provides the content of the text field.

Arguments may be passed to tokenizer factories by setting attributes on the `<tokenizer>` element.

```
<fieldType name="semicolonDelimited" class="solr.TextField">
  <analyzer type="query">
    <tokenizer class="solr.PatternTokenizerFactory" pattern=";" />
  </analyzer>
</fieldType>
```

The following sections describe the tokenizer factory classes included in this release of Solr.

For more information about Solr's tokenizers, see <http://wiki.apache.org/solr/AnalyzersTokenizersTokenFilters>.

Tokenizers discussed in this section:

- [Standard Tokenizer](#)
- [Classic Tokenizer](#)
- [Keyword Tokenizer](#)
- [Letter Tokenizer](#)
- [Lower Case Tokenizer](#)
- [N-Gram Tokenizer](#)
- [Edge N-Gram Tokenizer](#)
- [ICU Tokenizer](#)
- [Path Hierarchy Tokenizer](#)
- [Regular Expression Pattern Tokenizer](#)
- [UAX29 URL Email Tokenizer](#)
- [White Space Tokenizer](#)

Standard Tokenizer

This tokenizer splits the text field into tokens, treating whitespace and punctuation as delimiters. Delimiter characters are discarded, with the following exceptions:

- Periods (dots) that are not followed by whitespace are kept as part of the token.
- Words are split at hyphens, unless there is a number in the word, in which case the token is not split and the numbers and hyphen(s) are preserved.
- Recognizes Internet domain names and email addresses and preserves them as a single token.

The Standard Tokenizer supports [Unicode standard annex UAX#29](#) word boundaries with the following token types: <ALPHANUM>, <NUM>, <SOUTHEAST_ASIAN>, <IDEOGRAPHIC>, and <HIRAGANA>.

Factory class: solr.StandardTokenizerFactory

Arguments:

`maxTokenLength`: (integer, default 255) Solr ignores tokens that exceed the number of characters specified by `maxTokenLength`.

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
</analyzer>
```

In: "Please, email john.doe@foo.com by 03-09, re: m37-xq."

Out: "Please", "email", "john.doe@foo.com", "by", "03-09", "re", "m37-xq"

Classic Tokenizer

The Classic Tokenizer preserves the same behavior as the Standard Tokenizer of Solr versions 3.1 and previous. It does not use the [Unicode standard annex UAX#29](#) word boundary rules that the Standard Tokenizer uses. This tokenizer splits the text field into tokens, treating whitespace and punctuation as delimiters. Delimiter characters are discarded, with the following exceptions:

- Periods (dots) that are not followed by whitespace are kept as part of the token.
- Words are split at hyphens, unless there is a number in the word, in which case the token is not split and the numbers and hyphen(s) are preserved.
- Recognizes Internet domain names and email addresses and preserves them as a single token.

Factory class: solr.ClassicTokenizerFactory

Arguments:

maxTokenLength: (integer, default 255) Solr ignores tokens that exceed the number of characters specified by `maxTokenLength`.

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
</analyzer>
```

In: "Please, email john.doe@foo.com by 03-09, re: m37-xq."

Out: "Please", "email", "john.doe@foo.com", "by", "03-09", "re", "m37-xq"

Keyword Tokenizer

This tokenizer treats the entire text field as a single token.

Factory class: solr.KeywordTokenizerFactory

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.KeywordTokenizerFactory"/>
</analyzer>
```

In: "Please, email john.doe@foo.com by 03-09, re: m37-xq."

Out: "Please, email john.doe@foo.com by 03-09, re: m37-xq."

Letter Tokenizer

This tokenizer creates tokens from strings of contiguous letters, discarding all non-letter characters.

Factory class: `solr.LetterTokenizerFactory`

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.LetterTokenizerFactory"/>
</analyzer>
```

In: "I can't."

Out: "I", "can", "t"

Lower Case Tokenizer

Tokenizes the input stream by delimiting at non-letters and then converting all letters to lowercase. Whitespace and non-letters are discarded.

Factory class: `solr.LowerCaseTokenizerFactory`

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.LowerCaseTokenizerFactory"/>
</analyzer>
```

In: "I just **LOVE** my iPhone!"

Out: "i", "just", "love", "my", "iphone"

N-Gram Tokenizer

Reads the field text and generates n-gram tokens of sizes in the given range.

Factory class: `solr.NGramTokenizerFactory`

Arguments:

`minGramSize`: (integer, default 1) The minimum n-gram size, must be > 0.

`maxGramSize`: (integer, default 2) The maximum n-gram size, must be >= `minGramSize`.

Example:

Default behavior. Note that this tokenizer operates over the whole field. It does not break the field at whitespace. As a result, the space character is included in the encoding.

```
<analyzer>
  <tokenizer class="solr.NGramTokenizerFactory" />
</analyzer>
```

In: "hey man"

Out: "h", "e", "y", " ", "m", "a", "n", "he", "ey", "y ", " m", "ma", "an"

Example:

With an n-gram size range of 4 to 5:

```
<analyzer>
  <tokenizer class="solr.NGramTokenizerFactory" minGramSize="4" maxGramSize="5" />
</analyzer>
```

In: "bicycle"

Out: "bicy", "icyc", "cycl", "ycle", "bicyc", "icycl", "cycle"

Edge N-Gram Tokenizer

Reads the field text and generates edge n-gram tokens of sizes in the given range.

Factory class: `solr.EdgeNGramTokenizerFactory`

Arguments:

minGramSize: (integer, default 1) The minimum n-gram size, must be > 0.

maxGramSize: (integer, default 1) The maximum n-gram size, must be >= maxGramSize.

side: ("front" or "back", default "front") Whether to compute the n-grams from the beginning (front) of the text or from the end (back).

Example:

Default behavior (min and max default to 1):

```
<analyzer>
  <tokenizer class="solr.EdgeNGramTokenizerFactory" />
</analyzer>
```

In: "babaloo"

Out: "b"

Example:

Edge n-gram range of 2 to 5

```
<analyzer>
  <tokenizer class="solr.EdgeNGramTokenizerFactory" minGramSize="2" maxGramSize="5" />
</analyzer>
```

In: "babaloo"

Out: "ba", "bab", "baba", "babal"

Example:

Edge n-gram range of 2 to 5, from the back side:

```
<analyzer>
  <tokenizer class="solr.EdgeNGramTokenizerFactory" minGramSize="2" maxGramSize="5"
  side="back" />
</analyzer>
```

In: "babaloo"

Out: "oo", "loo", "aloo", "baloo"

ICU Tokenizer

This tokenizer processes multilingual text and tokenizes it appropriately based on its script attribute.

Factory class: solr.ICUTokenizerFactory

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.ICUTokenizerFactory"/>
</analyzer>
```

In: "Testing ""

Out: "Testing", "", "", "" "

Path Hierarchy Tokenizer

This tokenizer creates synonyms from file path hierarchies.

Factory class: solr.PathHierarchyTokenizerFactory

Arguments:

delimiter: (character, no default) You can specify the file path delimiter and replace it with a delimiter you provide. This can be useful for working with backslash delimiters.

replace: (character, no default) Specifies the delimiter character Solr uses in the tokenized output.

Example:

```
<fieldType name="text_path" class="solr.TextField" positionIncrementGap="100">
  <analyzer>
    <tokenizer class="solr.PathHierarchyTokenizerFactory" delimiter="\" replace="/" />
  </analyzer>
</fieldType>
```

In: "c:\usr\local\apache"

Out: "c:", "c:/usr", "c:/usr/local", "c:/usr/local/apache"

Regular Expression Pattern Tokenizer

This tokenizer uses a Java regular expression to break the input text stream into tokens. The expression provided by the pattern argument can be interpreted either as a delimiter that separates tokens, or to match patterns that should be extracted from the text as tokens.

See the Javadocs for [java.util.regex.Pattern](#) for more information on Java regular expression syntax.

Factory class: `solr.PatternTokenizerFactory`

Arguments:

pattern: (Required) The regular expression, as defined by in `java.util.regex.Pattern`.

group: (Optional, default -1) Specifies which regex group to extract as the token(s). The value -1 means the regex should be treated as a delimiter that separates tokens. Non-negative group numbers (≥ 0) indicate that character sequences matching that regex group should be converted to tokens. Group zero refers to the entire regex, groups greater than zero refer to parenthesized sub-expressions of the regex, counted from left to right.

Example:

A comma separated list. Tokens are separated by a sequence of zero or more spaces, a comma, and zero or more spaces.

```
<analyzer>
  <tokenizer class="solr.PatternTokenizerFactory" pattern="\s*,\s*" />
</analyzer>
```

In: "fee, fie, foe, fum, foo"

Out: "fee", "fie", "foe", "fum", "foo"

Example:

Extract simple, capitalized words. A sequence of at least one capital letter followed by zero or more letters of either case is extracted as a token.

```
<analyzer>
  <tokenizer class="solr.PatternTokenizerFactory" pattern="\[A-Z\]\[A-Za-z\]"
  group="0" />
</analyzer>
```

In: "Hello. My name is Inigo Montoya. You killed my father. Prepare to die."

Out: "Hello", "My", "Inigo", "Montoya". "You", "Prepare"

Example:

Extract part numbers which are preceded by "SKU", "Part" or "Part Number", case sensitive, with an optional semi-colon separator. Part numbers must be all numeric digits, with an optional hyphen. Regex capture groups are numbered by counting left parenthesis from left to right. Group 3 is the subexpression "[0-9-]+", which matches one or more digits or hyphens.

```
<analyzer>
  <tokenizer class="solr.PatternTokenizerFactory"
  pattern="(SKU|Part(\sNumber)?):?\s(\[0-9-\])" group="3" />
</analyzer>
```

In: "SKU: 1234, Part Number 5678, Part: 126-987"

Out: "1234", "5678", "126-987"

UAX29 URL Email Tokenizer

This tokenizer splits the text field into tokens, treating whitespace and punctuation as delimiters. Delimiter characters are discarded, with the following exceptions:

- Periods (dots) that are not followed by whitespace are kept as part of the token.
- Words are split at hyphens, unless there is a number in the word, in which case the token is not split and the numbers and hyphen(s) are preserved.
- Recognizes top-level (.com) Internet domain names; email addresses; `file:///`, `http(s)://`, and `ftp://` addresses; IPv4 and IPv6 addresses; and preserves them as a single token.

The UAX29 URL Email Tokenizer supports [Unicode standard annex UAX#29](#) word boundaries with the following token types: <ALPHANUM>, <NUM>, URL, EMAIL, <SOUTHEAST_ASIAN>, <IDEOGRAPHIC>, and <HIRAGANA>.

Factory class: `solr.UAX29URLEmailTokenizerFactory`

Arguments:

`maxTokenLength`: (integer, default 255) Solr ignores tokens that exceed the number of characters specified by `maxTokenLength`.

Example:

```
<analyzer>
  <tokenizer class="solr.UAX29URLEmailTokenizerFactory" />
</analyzer>
```

In: "Visit <http://accarol.com/contact.htm?from=external&a=10> or e-mail bob.cratchet@accarol.com"

Out: "Visit", "http://accarol.com/contact.htm?from=external&a=10", "or", "email", "bob.cratchet@accarol.com"

White Space Tokenizer

Simple tokenizer that splits the text stream on whitespace and returns sequences of non-whitespace characters as tokens. Note that any punctuation *will* be included in the tokenization.

Factory class: `solr.WhitespaceTokenizerFactory`

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory" />
</analyzer>
```

In: "To be, or what?"

Out: "To", "be,", "or", "what?"

Filter Descriptions

You configure each filter with a `<filter>` element in `schema.xml` as a child of `<analyzer>`, following the `<tokenizer>` element. Filter definitions should follow a tokenizer or another filter definition because they take a `TokenStream` as input. For example.

```
<fieldType name="text" class="solr.TextField">
  <analyzer type="index">
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>...
  </analyzer>
</fieldType>
```

The class attribute names a factory class that will instantiate a filter object as needed. Filter factory classes must implement the `org.apache.solr.analysis.TokenFilterFactory` interface. Like tokenizers, filters are also instances of `TokenStream` and thus are producers of tokens. Unlike tokenizers, filters also consume tokens from a `TokenStream`. This allows you to mix and match filters, in any order you prefer, downstream of a tokenizer.

Arguments may be passed to tokenizer factories to modify their behavior by setting attributes on the `<filter>` element. For example:

```
<fieldType name="semicolonDelimited" class="solr.TextField">
  <analyzer type="query">
    <tokenizer class="solr.PatternTokenizerFactory" pattern="; " />
    <filter class="solr.LengthFilterFactory" *min="2" max="7"/>
  </analyzer>
</fieldType>
```

The following sections describe the filter factories that are included in this release of Solr.

For more information about Solr's filters, see <http://wiki.apache.org/solr/AnalyzersTokenizersTokenFilters>.

Filters discussed in this section:

- [ASCII Folding Filter](#)
- [Classic Filter](#)
- [Common Grams Filter](#)
- [Collation Key Filter](#)
- [Edge N-Gram Filter](#)
- [English Minimal Stem Filter](#)
- [Hyphenated Words Filter](#)
- [ICU Folding Filter](#)
- [ICU Normalizer 2 Filter](#)
- [ICU Transform Filter](#)
- [Keep Words Filter](#)
- [KStem Filter](#)
- [Length Filter](#)
- [Lower Case Filter](#)
- [N-Gram Filter](#)
- [Numeric Payload Token Filter](#)
- [Pattern Replace Filter](#)
- [Phonetic Filter](#)
- [Porter Stem Filter](#)
- [Position Filter Factory](#)
- [Remove Duplicates Token Filter](#)
- [Reversed Wildcard Filter](#)
- [Shingle Filter](#)
- [Snowball Porter Stemmer Filter](#)
- [Standard Filter](#)
- [Stop Filter](#)
- [Synonym Filter](#)
- [Token Offset Payload Filter](#)
- [Trim Filter](#)
- [Type As Payload Filter](#)
- [Word Delimiter Filter](#)

ASCII Folding Filter

This filter converts alphabetic, numeric, and symbolic Unicode characters which are not in the Basic Latin Unicode block (the first 127 ASCII characters) to their ASCII equivalents, if one exists. This filter converts characters from the following Unicode blocks:

- [C1 Controls and Latin-1 Supplement](#) (PDF)
- [Latin Extended-A](#) (PDF)
- [Latin Extended-B](#) (PDF)
- [Latin Extended Additional](#) (PDF)
- [Latin Extended-C](#) (PDF)
- [Latin Extended-D](#) (PDF)
- [IPA Extensions](#) (PDF)
- [Phonetic Extensions](#) (PDF)
- [Phonetic Extensions Supplement](#) (PDF)
- [General Punctuation](#) (PDF)
- [Superscripts and Subscripts](#) (PDF)
- [Enclosed Alphanumerics](#) (PDF)
- [Dingbats](#) (PDF)
- [Supplemental Punctuation](#) (PDF)
- [Alphabetic Presentation Forms](#) (PDF)
- [Halfwidth and Fullwidth Forms](#) (PDF)

Factory class: solr.ASCIIFilterFactory

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.ASCIIFilterFactory"/>
</analyzer>
```

In: "á" (Unicode character 00E1)

Out: "a" (ASCII character 160)

Classic Filter

This filter takes the output of the [Classic Tokenizer](#) and strips periods from acronyms and "'s" from possessives.

Factory class: solr.ClassicFilterFactory

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.ClassicTokenizerFactory"/>
  <filter class="solr.ClassicFilterFactory"/>
</analyzer>
```

In: "I.B.M. cat's can't"

Tokenizer to Filter: "I.B.M", "cat's", "can't"

Out: "IBM", "cat", "can't"

Common Grams Filter

This filter creates word shingles by combining common tokens such as stop words with regular tokens. This is useful for creating phrase queries containing common words, such as "the cat." Solr normally ignores stop words in queried phrases, so searching for "the cat" would return all matches for the word "cat."

Factory class: solr.CommonGramsFilterFactory

Arguments:

words: (a common word file in .txt format) Provide the name of a common word file, such as stopwords.txt.

ignoreCase: (boolean) If true, the filter ignores the case of words when comparing them to the common word file.

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.CommonGramsFilterFactory" words="stopwords.txt"
  ignoreCase="true"/>
</analyzer>
```

In: "the Cat"

Tokenizer to Filter: "the", "Cat"

Out: "the_cat"

Collation Key Filter

See [Unicode Collation](#)

Edge N-Gram Filter

This filter generates edge n-gram tokens of sizes within the given range.

Factory class: solr.EdgeNGramFilterFactory

Arguments:

minGramSize: (integer, default 1) The minimum gram size.

maxGramSize: (integer, default 1) The maximum gram size.

Example:

Default behavior.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.EdgeNGramFilterFactory"/>
</analyzer>
```

In: "four score and twenty"

Tokenizer to Filter: "four", "score", "and", "twenty"

Out: "f", "s", "a", "t"

Example:

A range of 1 to 4.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.EdgeNGramFilterFactory" minGramSize="1" maxGramSize="4"/>
</analyzer>
```

In: "four score"

Tokenizer to Filter: "four", "score"

Out: "f", "fo", "fou", "four", "s", "sc", "sco", "scor"

Example:

A range of 4 to 6.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.EdgeNGramFilterFactory" minGramSize="4" maxGramSize="6"/>
</analyzer>
```

In: "four score and twenty"

Tokenizer to Filter: "four", "score", "and", "twenty"

Out: "four", "sco", "scor"

English Minimal Stem Filter

This filter stems plural English words to their singular form.

Factory class: solr.EnglishMinimalStemFilterFactory

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.EnglishMinimalStemFilterFactory"/>
</analyzer>
```

In: "dogs cats"

Tokenizer to Filter: "dogs", "cats"

Out: "dog", "cat"

Hyphenated Words Filter

This filter reconstructs hyphenated words that have been tokenized as two tokens because of a line break or other intervening whitespace in the field text. If a token ends with a hyphen, it is joined with the following token and the hyphen is discarded. Note that for this filter to work properly, the upstream tokenizer must not remove trailing hyphen characters. This filter is generally only useful at index time.

Factory class: solr.HyphenatedWordsFilterFactory

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.HyphenatedWordsFilterFactory"/>
</analyzer>
```

In: "A hyphen- ated word"

Tokenizer to Filter: "A", "hyphen-", "ated", "word"

Out: "A", "hyphenated", "word"

ICU Folding Filter

This filter is a custom Unicode normalization form that applies the foldings specified in [Unicode Technical Report 30](#) in addition to the `NFKC_Casefold` normalization form as described in [ICU Normalizer 2 Filter](#). This filter is a better substitute for the combined behavior of the [ASCII Folding Filter](#), [Lower Case Filter](#), and [ICU Normalizer 2 Filter](#).

To use this filter, see `solr/contrib/analysis-extras/README.txt` for instructions on which jars you need to add to your `solr_home/lib`.

Factory class: `solr.ICUFoldingFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ICUFoldingFilterFactory"/>
</analyzer>
```

For detailed information on this normalization form, see <http://www.unicode.org/reports/tr30/tr30-4.html>.

ICU Normalizer 2 Filter

This filter factory normalizes text according to one of five Unicode Normalization Forms as described in [Unicode Standard Annex #15](#):

- NFC: (`name="nfc" mode="compose"`) Normalization Form C, canonical decomposition
- NFD: (`name="nfc" mode="decompose"`) Normalization Form D, canonical decomposition, followed by canonical composition
- NFKC: (`name="nfkc" mode="compose"`) Normalization Form KC, compatibility decomposition

- NFKD: (name="nfkd" mode="decompose") Normalization Form KD, compatibility decomposition, followed by canonical composition
- NFKC_Casfold: (name="nfkc_cf" mode="compose") Normalization Form KC, with additional Unicode case folding. Using the ICU Normalizer 2 Filter is a better-performing substitution for the [Lower Case Filter](#) and NFKC normalization.

Factory class: solr.ICUNormalizer2FilterFactory

Arguments:

name: (string) The name of the normalization form; `nfkc`, `nfd`, `nfkc`, `nfkd`, `nfkc_cf`

mode: (string) The mode of Unicode character composition and decomposition; `compose` or `decompose`

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ICUNormalizer2FilterFactory"/>
</analyzer>
```

For detailed information about these Unicode Normalization Forms, see <http://unicode.org/reports/tr15/>.

To use this filter, see `solr/contrib/analysis-extras/README.txt` for instructions on which jars you need to add to your `solr_home/lib`.

ICU Transform Filter

This filter applies [ICU Transforms](#) to text. This filter supports only ICU System Transforms. Custom rule sets are not supported.

Factory class: solr.ICUTransformFilterFactory

Arguments:

id: (string) The identifier for the ICU System Transform you wish to apply with this filter. For a full list of ICU System Transforms, see http://demo.icu-project.org/icu-bin/translit?TEMPLATE_FILE=data/translit_rule_main.html.

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ICUTransformFilterFactory" id="Traditional-Simplified"/>
</analyzer>
```

For detailed information about ICU Transforms, see <http://userguide.icu-project.org/transforms/general>.

To use this filter, see `solr/contrib/analysis-extras/README.txt` for instructions on which jars you need to add to your `solr_home/lib`.

Keep Words Filter

This filter discards all tokens except those that are listed in the given word list. This is the inverse of the Stop Words Filter. This filter can be useful for building specialized indices for a constrained set of terms.

Factory class: `solr.KeepWordFilterFactory`

Arguments:

words: (required) Path of a text file containing the list of keep words, one per line. Blank lines and lines that begin with "#" are ignored. This may be an absolute path, or a simple filename in the Solr config directory.

ignoreCase: (true/false) If **true** then comparisons are done case-insensitively. If this argument is true, then the words file is assumed to contain only lowercase words. The default is **false**.

Example:

Where `keepwords.txt` contains:

happy

funny

silly

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.KeepWordFilterFactory" words="keepwords.txt"/>
</analyzer>
```

In: "Happy, sad or funny"

Tokenizer to Filter: "Happy", "sad", "or", "funny"

Out: "funny"

Example:

Same `keywords.txt`, case insensitive:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.KeepWordFilterFactory" words="keywords.txt" ignoreCase="true"/>
</analyzer>
```

In: "Happy, sad or funny"

Tokenizer to Filter: "Happy", "sad", "or", "funny"

Out: "Happy", "funny"

Example:

Using `LowerCaseFilterFactory` before filtering for keep words, no `ignoreCase` flag.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.KeepWordFilterFactory" words="keywords.txt"/>
</analyzer>
```

In: "Happy, sad or funny"

Tokenizer to Filter: "Happy", "sad", "or", "funny"

Filter to Filter: "happy", "sad", "or", "funny"

Out: "happy", "funny"

KStem Filter

KStem is an alternative to the Porter Stem Filter for developers looking for a less aggressive stemmer. KStem was written by Bob Krovetz, ported to Lucene by Sergio Guzman-Lara (UMASS Amherst). This stemmer is only appropriate for English language text.

Factory class: `solr.KStemFilterFactory`

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory" />
  <filter class="solr.KStemFilterFactory" />
</analyzer>
```

In: "jump jumping jumped"

Tokenizer to Filter: "jump", "jumping", "jumped"

Out: "jump", "jump", "jump"

Length Filter

This filter passes tokens whose length falls within the min/max limit specified. All other tokens are discarded.

Factory class: solr.LengthFilterFactory

Arguments:

min: (integer, required) Minimum token length. Tokens shorter than this are discarded.

max: (integer, required, must be \geq min) Maximum token length. Tokens longer than this are discarded.

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory" />
  <filter class="solr.LengthFilterFactory" min="3" max="7" />
</analyzer>
```

In: "turn right at Albuquerque"

Tokenizer to Filter: "turn", "right", "at", "Albuquerque"

Out: "turn", "right"

Lower Case Filter

Converts any uppercase letters in a token to the equivalent lowercase token. All other characters are left unchanged.

Factory class: solr.LowerCaseFilterFactory

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.LowerCaseFilterFactory"/>
</analyzer>
```

In: "Down With CamelCase"

Tokenizer to Filter: "Down", "With", "CamelCase"

Out: "down", "with", "camelcase"

N-Gram Filter

Generates n-gram tokens of sizes in the given range.

Factory class: solr.NGramFilterFactory

Arguments:

minGramSize: (integer, default 1) The minimum gram size.

maxGramSize: (integer, default 2) The maximum gram size.

Example:

Default behavior.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.NGramFilterFactory"/>
</analyzer>
```

In: "four score"

Tokenizer to Filter: "four", "score"

Out: "f", "o", "u", "r", "fo", "ou", "ur", "s", "c", "o", "r", "e", "sc", "co", "or", "re"

Example:

A range of 1 to 4.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.NGramFilterFactory" *minGramSize="1" maxGramSize="4"/>
</analyzer>
```

In: "four score"

Tokenizer to Filter: "four", "score"

Out: "f", "fo", "fou", "four", "s", "sc", "sco", "scor"

Example:

A range of 3 to 5.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.NGramFilterFactory" *minGramSize="3" maxGramSize="5"/>
</analyzer>
```

In: "four score"

Tokenizer to Filter: "four", "score"

Out: "fou", "our", "four", "sco", "cor", "ore", "scor", "core", "score"

Numeric Payload Token Filter

This filter adds a numeric floating point payload value to tokens that match a given type. Refer to the Javadoc for the `org.apache.lucene.analysis.Token` class for more information about token types and payloads.

Factory class: `solr.NumericPayloadTokenFilterFactory`

Arguments:

`payload`: (required) A floating point value that will be added to all matching tokens.

`typeMatch`: (required) A token type name string. Tokens with a matching type name will have their payload set to the above floating point value.

Example:

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.NumericPayloadTokenFilterFactory" payload="0.75"
typeMatch="word"/>
</analyzer>
```

In: "bing bang boom"

Tokenizer to Filter: "bing", "bang", "boom"

Out: "bing"[0.75], "bang"[0.75], "boom"[0.75]

Pattern Replace Filter

This filter applies a regular expression to each token and, for those that match, substitutes the given replacement string in place of the matched pattern. Tokens which do not match are passed though unchanged.

Factory class: solr.PatternReplaceFilter

Arguments:

pattern: (required) The regular expression to test against each token, as per `java.util.regex.Pattern`.

replacement: (required) A string to substitute in place of the matched pattern. This string may contain references to capture groups in the regex pattern. See the Javadoc for `java.util.regex.Matcher`.

replace: ("all" or "first", default "all") Indicates whether all occurrences of the pattern in the token should be replaced, or only the first.

Example:

Simple string replace:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.PatternReplaceFilter" pattern="cat" replacement="dog"/>
</analyzer>
```

In: "cat concatenate catycat"

Tokenizer to Filter: "cat", "concatenate", "catycat"

Out: "dog", "condogenate", "dogydog"

Example:

String replacement, first occurrence only:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.PatternReplaceFilter" pattern="cat" replacement="dog"
*replace="first"/>
</analyzer>
```

In: "cat concatenate catycat"

Tokenizer to Filter: "cat", "concatenate", "catycat"

Out: "dog", "condogenate", "dogycat"

Example:

More complex pattern with capture group reference in the replacement. Tokens that start with non-numeric characters and end with digits will have an underscore inserted before the numbers. Otherwise the token is passed through.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.PatternReplaceFilter" pattern="(\D+)(\d+)$" replacement="$1_$2"/>
</analyzer>
```

In: "cat foo1234 9987 blah1234foo"

Tokenizer to Filter: "cat", "foo1234", "9987", "blah1234foo"

Out: "cat", "foo_1234", "9987", "blah1234foo"

Phonetic Filter

This filter creates tokens using one of the phonetic encoding algorithms in the `org.apache.commons.codec.language` package.

Factory class: `solr.PhoneticFilterFactory`

Arguments:

`encoder`: (required) The name of the encoder to use. The encoder name must be one of the following (case insensitive):

"DoubleMetaphone", "Metaphone", "Soundex", "RefinedSoundex", or "Caverphone"

inject: (true/false) If true (the default), then new phonetic tokens are added to the stream. Otherwise, tokens are replaced with the phonetic equivalent. Setting this to false will enable phonetic matching, but the exact spelling of the target word may not match.

maxCodeLength: (integer) The maximum length of the code to be generated by the Metaphone or Double Metaphone encoders.

Example:

Default behavior for DoubleMetaphone encoding.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.PhoneticFilterFactory" encoder="DoubleMetaphone"/>
</analyzer>
```

In: "four score and twenty"

Tokenizer to Filter: "four"(1), "score"(2), "and"(3), "twenty"(4)

Out: "four"(1), "FR"(1), "score"(2), "SKR"(2), "and"(3), "ANT"(3), "twenty"(4), "TNT"(4)

The phonetic tokens have a position increment of 0, which indicates that they are at the same position as the token they were derived from (immediately preceding).

Example:

Discard original token.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.PhoneticFilterFactory" encoder="DoubleMetaphone"
  *inject="false"/>
</analyzer>
```

In: "four score and twenty"

Tokenizer to Filter: "four"(1), "score"(2), "and"(3), "twenty"(4)

Out: "FR"(1), "SKR"(2), "ANT"(3), "TWNT"(4)

Example:

Default Soundex encoder.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.PhoneticFilterFactory" *encoder="Soundex"/>
</analyzer>
```

In: "four score and twenty"

Tokenizer to Filter: "four"(1), "score"(2), "and"(3), "twenty"(4)

Out: "four"(1), "F600"(1), "score"(2), "S600"(2), "and"(3), "A530"(3), "twenty"(4), "T530"(4)

Porter Stem Filter

This filter applies the Porter Stemming Algorithm for English. The results are similar to using the Snowball Porter Stemmer with the `language="English"` argument. But this stemmer is coded directly in Java and is not based on Snowball. Nor does it accept a list of protected words. This stemmer is only appropriate for English language text.

Factory class: `solr.PorterStemFilterFactory`

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory" />
  <filter class="solr.PorterStemFilterFactory" />
</analyzer>
```

In: "jump jumping jumped"

Tokenizer to Filter: "jump", "jumping", "jumped"

Out: "jump", "jump", "jump"

Position Filter Factory

This filter sets the position increment values of all tokens in a token stream except the first, which retains its original position increment value.

Factory class: `solr.PositionIncrementFilterFactory`

Arguments:

`positionIncrement:` (integer, default = 0) The position increment value to apply to all tokens in a token stream except the first.

Example:

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.PositionFilterFactory" positionIncrement="1"/>
</analyzer>
```

In: "hello world"**Tokenizer to Filter:** "hello", "world"**Out:** "hello" (token position 1), "world" (token position 3)

Remove Duplicates Token Filter

The filter removes duplicate tokens in the stream. Tokens are considered to be duplicates if they have the same text and position values.

Factory class: solr.RemoveDuplicatesTokenFilterFactory**Arguments:** None**Example:**

This is an artificial example that uses the [Synonym Filter](#) to generate duplicate symbols, which are then removed. The file `testsyns.txt` contains the following:

```
blurt => foo,fooblort => bar,bar
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.SynonymFilterFactory" synonyms="testsyns.txt"/>
  <filter class="solr.RemoveDuplicatesTokenFilterFactory"/>
</analyzer>
```

In: "blurt blort"**Tokenizer to Filter:** "blurt"(1), "blurt"(2)**Tokenizer to Filter:** "foo"(1), "foo"(1), "bar"(2), "bar"(2)**Out:** "foo"(1), "bar"(2)

Reversed Wildcard Filter

This filter reverses tokens to provide faster leading wildcard and prefix queries. Tokens without wildcards are not reversed.

Factory class: solr.ReversedWildcardFilterFactory

Arguments:

`withOriginal` (boolean) If true, the filter produces both original and reversed tokens at the same positions. If false, produces only reversed tokens.

`maxPosAsterisk` (integer, default = 2) The maximum position of the asterisk wildcard ('*') that triggers the reversal of the query term. Terms with asterisks at positions above this value are not reversed.

`maxPosQuestion` (integer, default = 1) The maximum position of the question mark wildcard ('?') that triggers the reversal of query term. To reverse only pure suffix queries (queries with a single leading asterisk), set this to 0 and `maxPosAsterisk` to 1.

`maxFractionAsterisk` (float, default = 0.0) An additional parameter that triggers the reversal if asterisk ('*') position is less than this fraction of the query token length.

`minTrailing` (integer, default = 2) The minimum number of trailing characters in a query token after the last wildcard character. For good performance this should be set to a value larger than 1.

Example:

```
<analyzer type="index">
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.ReversedWildcardFilterFactory" withOriginal="true"
    maxPosAsterisk="2" maxPosQuestion="1" minTrailing="2" maxFractionAsterisk="0"/>
</analyzer>
```

In: "*foo *bar"

Tokenizer to Filter: "*foo", "*bar"

Out: "oof*", "rab*"

Shingle Filter

This filter constructs shingles, which are token n-grams, from the token stream. It combines runs of tokens into a single token.

Factory class: solr.ShingleFilterFactory

Arguments:

`maxShingleSize`: (integer, must be ≥ 2 , default 2) The maximum number of tokens per shingle.

outputUnigrams: (true/false) If true (the default), then each individual token is also included at its original position.

Example:

Default behavior.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ShingleFilterFactory"/>
</analyzer>
```

In: "To be, or what?"

Tokenizer to Filter: "To"(1), "be"(2), "or"(3), "what"(4)

Out: "To"(1), "To be"(1), "be"(2), "be or"(2), "or"(3), "or what"(3), "what"(4)

Example:

A shingle size of four, do not include original token.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ShingleFilterFactory" maxShingleSize="4" outputUnigrams="false"/>
</analyzer>
```

In: "To be, or not to be."

Tokenizer to Filter: "To"(1), "be"(2), "or"(3), "not"(4), "to"(5), "be"(6)

Out: "To be"(1), "To be or"(1), "To be or not"(1), "be or"(2), "be or not"(2), "be or not to"(2), "or not"(3), "or not to"(3), "or not to be"(3), "not to"(4), "not to be"(4), "to be"(5)

Snowball Porter Stemmer Filter

This filter factory instantiates a language-specific stemmer generated by Snowball. Snowball is a software package that generates pattern-based word stemmers. This type of stemmer is not as accurate as a table-based stemmer, but is faster and less complex. Table-driven stemmers are labor intensive to create and maintain and so are typically commercial products.

This release of Solr contains Snowball stemmers for Armenian, Basque, Catalan, Danish, Dutch, English, Finnish, French, German, Hungarian, Italian, Norwegian, Portuguese, Romanian, Russian, Spanish, Swedish and Turkish. For more information on Snowball, visit

<http://snowball.tartarus.org/>.

Factory class: solr.SnowballPorterFilterFactory

Arguments:

language: (default "English") The name of a language, used to select the appropriate Porter stemmer to use. Case is significant. This string is used to select a package name in the "org.tartarus.snowball.ext" class hierarchy.

protected: Path of a text file containing a list of protected words, one per line. Protected words will not be stemmed. Blank lines and lines that begin with "#" are ignored. This may be an absolute path, or a simple file name in the Solr config directory.

Example:

Default behavior:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.SnowballPorterFilterFactory"/>
</analyzer>
```

In: "flip flipped flipping"

Tokenizer to Filter: "flip", "flipped", "flipping"

Out: "flip", "flip", "flip"

Example:

French stemmer, English words:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.SnowballPorterFilterFactory" language="French"/>
</analyzer>
```

In: "flip flipped flipping"

Tokenizer to Filter: "flip", "flipped", "flipping"

Out: "flip", "flipped", "flipping"

Example:

Spanish stemmer, Spanish words:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.SnowballPorterFilterFactory" language="Spanish"/>
</analyzer>
```

In: "cante canta"

Tokenizer to Filter: "cante", "canta"

Out: "cant", "cant"

Standard Filter

This filter removes dots from acronyms and the substring "'s" from the end of tokens. This filter depends on the tokens being tagged with the appropriate term-type to recognize acronyms and words with apostrophes.

Factory class: solr.StandardFilterFactory

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.StandardFilterFactory"/>
</analyzer>
```

In: "Bob's I.O.U."

Tokenizer to Filter: "Bob's", "I.O.U."

Out: "Bob". "IOU"

Stop Filter

This filter discards, or *stops* analysis of, tokens that are on the given stop words list. A standard stop words list is included in the Solr config directory, named stopwords.txt, which is appropriate for typical English language text.

Factory class: solr.StopFilterFactory

Arguments:

words: (optional) The path of a file that contains a list of stop words, one per line. Blank lines and lines that begin with "#" are ignored. This may be an absolute path, or path relative to the Solr config directory.

ignoreCase: (true/false, default false) Ignore case when testing for stop words. If true, the stop list should contain lowercase words.

enablePositionIncrements: (true/false, default false) When true, if a token is stopped (discarded) then the position of the following token is incremented.

Example:

Case-sensitive matching, capitalized words not stopped. Token positions skip stopped words.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.StopFilterFactory" words="stopwords.txt"/>
</analyzer>
```

In: "To be or what?"

Tokenizer to Filter: "To"(1), "be"(2), "or"(3), "what"(4)

Out: "To"(1), "what"(2)

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.StopFilterFactory" words="stopwords.txt" ignoreCase="true"/>
</analyzer>
```

In: "To be or what?"

Tokenizer to Filter: "To"(1), "be"(2), "or"(3), "what"(4)

Out: "what"(1)

Example:

Position increment enabled, original positions retained. No tokens at positions of stopped words.

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.StopFilterFactory" words="stopwords.txt" ignoreCase="true"
enablePositionIncrements="true"/>
</analyzer>
```

In: "You are a star"

Tokenizer to Filter: "You"(1), "are"(2), "a"(3), "star"(4)

Out: "You"(1), "star"(4)

Synonym Filter

This filter does synonym mapping. Each token is looked up in the list of synonyms and if a match is found, then the synonym is emitted in place of the token. The position value of the new tokens are set such they all occur at the same position as the original token.

Factory class: solr.SynonymFilterFactory

Arguments:

synonyms: (required) The path of a file that contains a list of synonyms, one per line. Blank lines and lines that begin with "#" are ignored. This may be an absolute path, or path relative to the Solr config directory. There are two ways to specify synonym mappings:

- A comma-separated list of words. If the token matches any of the words, then all the words in the list are substituted, which will include the original token.
- Two comma-separated lists of words with the symbol "=>" between them. If the token matches any word on the left, then the list on the right is substituted. The original token will not be included unless it is also in the list on the right.

For the following examples, assume the following `synonyms.txt` file:

```
couch,sofa,divan
teh => the
huge,ginormous,humungous => large
small => tiny,teeny,weeny
```

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.SynonymFilterFactory" synonyms="mysynonyms.txt"/>
</analyzer>
```

In: "teh small couch"

Tokenizer to Filter: "teh"(1), "small"(2), "couch"(3)

Out: "the"(1), "tiny"(2), "teeny"(2), "weeny"(2), "couch"(3), "sofa"(3), "divan"(3)

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.SynonymFilterFactory" synonyms="mysynonyms.txt"/>
</analyzer>
```

In: "teh ginormous, humungous sofa"

Tokenizer to Filter: "teh"(1), "ginormous"(2), "humungous"(3), "sofa"(4)

Out: "the"(1), "large"(2), "large"(3), "couch"(4), "sofa"(4), "divan"(4)

Token Offset Payload Filter

This filter adds the numeric character offsets of the token as a payload value for that token.

Factory class: solr.TokenOffsetPayloadTokenFilterFactory

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.TokenOffsetPayloadTokenFilterFactory"/>
</analyzer>
```

In: "bing bang boom"

Tokenizer to Filter: "bing", "bang", "boom"

Out: "bing"[0,4], "bang"[5,9], "boom"[10,14]

Trim Filter

This filter trims leading and/or trailing whitespace from tokens. Most tokenizers break tokens at whitespace, so this filter is most often used for special situations.

Factory class: solr.TrimFilterFactory

Arguments:

`updateOffsets`: (true/false, default false) If true, the token's start/end offsets are adjusted to account for any whitespace that was removed.

Example:

The PatternTokenizerFactory configuration used here splits the input on simple commas, it does not remove whitespace.

```
<analyzer>
  <tokenizer class="solr.PatternTokenizerFactory" pattern=","/>
  <filter class="solr.TrimFilterFactory"/>
</analyzer>
```

In: "one, two , three ,four "

Tokenizer to Filter: "one", " two ", " three ", "four "

Out: "one", "two", "three", "four"

Type As Payload Filter

This filter adds the token's type, as an encoded byte sequence, as its payload.

Factory class: solr.TypeAsPayloadTokenFilterFactory

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.TypeAsPayloadTokenFilterFactory"/>
</analyzer>
```

In: "Pay Bob's I.O.U."

Tokenizer to Filter: "Pay", "Bob's", "I.O.U."

Out: "Pay"[<ALPHANUM>], "Bob's"[<APOSTROPHE>], "I.O.U."[<ACRONYM>]

Word Delimiter Filter

This filter splits tokens at word delimiters. The rules for determining delimiters are determined as follows:

- A change in case within a word: "CamelCase" -> "Camel", "Case" This can be disabled by setting `splitOnCaseChange="0"` (see below).
- A transition from alpha to numeric characters or vice versa: "Gonzo5000" -> "Gonzo", "5000" ~~"4500XL"~~ -> "4500", "XL" This can be disabled by setting `splitOnNumerics="0"`.
- Non-alphanumeric characters (discarded): "hot-spot" -> "hot", "spot"
- A trailing "'s" is removed: "O'Reilly's" -> "O", "Reilly"
- Any leading or trailing delimiters are discarded: ~~"-hot-spot"~~ -> "hot", "spot"

Factory class: `solr.WordDelimiterFilterFactory`

Arguments:

`generateWordParts`: (integer, default 1) If non-zero, splits words at delimiters. For example: "CamelCase", "hot-spot" -> "Camel", "Case", "hot", "spot"

`generateNumberParts`: (integer, default 1) If non-zero, splits numeric strings at delimiters: "1947-32" -> "1947", "32"

`splitOnCaseChange`: (integer, default 1) If 0, words are not split on camel-case changes: "BugBlaster-XL" -> "BugBlaster", "XL" Example 1 below illustrates the default (non-zero) splitting behavior.

`splitOnNumerics`: (integer, default 1) If 0, don't split words on transitions from alpha to numeric: "FemBot3000" -> "Fem", "Bot3000"

`catenateWords`: (integer, default 0) If non-zero, maximal runs of word parts will be joined: "hot-spot-sensor's" -> "hotspotsensor"

`catenateNumbers`: (integer, default 0) If non-zero, maximal runs of number parts will be joined: "1947-32" -> "194732"

`catenateAll`: (0/1, default 0) If non-zero, runs of word and number parts will be joined: "Zap-Master-9000" -> "ZapMaster9000"

`preserveOriginal`: (integer, default 0) If non-zero, the original token is preserved:

"Zap-Master-9000" -> "Zap-Master-9000", "Zap", "Master", "9000"

`protected`: (optional) The pathname of a file that contains a list of protected words that should be passed though without splitting.

`stemEnglishPossessive`: (integer, default 1) If 1, strips the possessive "'s" from each subword.

Example:

Default behavior. The whitespace tokenizer is used here to preserve non-alphanumeric characters.

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.WordDelimiterFilterFactory"/>
</analyzer>
```

In: "hot-spot RoboBlaster/9000 100XL"

Tokenizer to Filter: "hot-spot", "RoboBlaster/9000", "100XL"

Out: "hot", "spot", "Robo", "Blaster", "9000", "100", "XL"

Example:

Do not split on case changes, and do not generate number parts. Note that by not generating number parts, tokens containing only numeric parts are ultimately discarded.

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.WordDelimiterFilterFactory" generateNumberParts="0"
splitOnCaseChange="0"/>
</analyzer>
```

In: "hot-spot RoboBlaster/9000 100-42"

Tokenizer to Filter: "hot-spot", "RoboBlaster/9000", "100-42"

Out: "hot", "spot", "RoboBlaster", "9000"

Example:

Concatenate word parts and number parts, but not word and number parts that occur in the same token.

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.WordDelimiterFilterFactory" catenateWords="1"
catenateNumbers="1"/>
</analyzer>
```

In: "hot-spot 100+42 XL40"

Tokenizer to Filter: "hot-spot"(1), "100+42"(2), "XL40"(3)

Out: "hot"(1), "spot"(2), "hotspot"(2), "100"(3), "42"(4), "10042"(4), "XL"(5), "40"(6)

Example:

Concatenate all. Word and/or number parts are joined together.

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.WordDelimiterFilterFactory" catenateAll="1"/>
</analyzer>
```

In: "XL-4000/ES"

Tokenizer to Filter: "XL-4000/ES"(1)

Out: "XL"(1), "4000"(2), "ES"(3), "XL4000ES"(3)

Example:

Using a protected words list that contains "AstroBlaster" and "XL-5000" (among others).

```
<analyzer>
  <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  <filter class="solr.WordDelimiterFilterFactory" protected="protwords.txt"/>
</analyzer>
```

In: "FooBar AstroBlaster XL-5000 ==ES-34-"

Tokenizer to Filter: "FooBar", "AstroBlaster", "XL-5000", "==ES-34-"

Out: "FooBar", "FooBar", "AstroBlaster", "XL-5000", "ES", "34"

CharFilterFactories

Char Filter is a component that pre-processes input characters. Char Filters can be chained like Token Filters and placed in front of a Tokenizer. **Char Filters** can add, change, or remove characters without worrying about fault of Token offsets.

For more information about Solr's Char Filters, see <http://wiki.apache.org/solr/AnalyzersTokenizersTokenFilters>.

solr.MappingCharFilterFactory

This filter creates `org.apache.lucene.analysis.MappingCharFilter`, which can be used for changing one character to another (for example, for normalizing é to e.)

solr.HTMLStripCharFilterFactory

This filter creates `org.apache.solr.analysis.HTMLStripCharFilter`. `HTMLStripCharFilter` strips HTML from the input stream and passes the result to either CharFilter or Tokenizer.

This filter:

- Removes HTML/XML tags while preserving other content.
- Removes attributes within tags and supports optional attribute quoting.
- Removes XML processing instructions, such as: `<?foo bar?>`
- Removes XML comments.
- Removes XML elements starting with `<!` and ending with `>`
- Removes contents of `<script>` and `<style>` elements.
- Handles XML comments inside these elements (normal comment processing will not always work).
- Replaces numeric character entities references like `A` or ``.
- The terminating `';` is optional if the entity reference is followed by whitespace.
- Replaces all named character entity references.
- ` ` is replaced with a space instead of `0xa0`.
- The terminating `';` is mandatory to avoid false matches on something like "Alpha&Omega Corp"

The input need not be an HTML document. The filter removes only constructs that look like HTML. If the input doesn't include anything that looks like HTML, the filter won't remove any input.

The table below presents examples of HTML stripping.

Input	Output
my link	my link
<?xml?> hello<!--comment-->	hello
hello<script><-- f('<!--internal--></script>'); --></script>	hello
if a<b then print a;	if a<b then print a;
hello <td height=22 nowrap align="left">	hello
a<b A Alpha&Omega	a<b A Alpha&Omega Ω

solrPatternReplaceCharFilterFactory

This filter uses [regular expressions](#) to replace or change character patterns.

You can configure this filter in `schema.xml` like this:

```
<fieldType name="textCharNorm" class="solr.TextField" positionIncrementGap="100" >
  <analyzer>
    <charFilter class="solr.PatternReplaceCharFilterFactory"
      pattern="([nN][oO]\.)\s*(\d+)"
      replaceWith="$1$2"/>
    <charFilter class="solr.MappingCharFilterFactory"
      mapping="mapping-ISOLatin1Accent.txt"/>
    <tokenizer class="solr.WhitespaceTokenizerFactory"/>
  </analyzer>
</fieldType>
```

The table below presents examples of regex-based pattern replacement:

Input	pattern	replaceWith	Output	Description
see-ing looking	(\w+)(ing)	1	see-ing look	Removes "ing" from the end of word.
see-ing looking	(\w+)ing	1	see-ing look	Same as above. 2nd parentheses can be omitted.

No.1 NO. no. 543	[nN][oO] \.\s*(\d+)	{#},1	#1 NO. #543	Example of literal. Do not forget to set a non-period <code>blockDelimiter</code> when using periods in patterns.
abc=1234=5678	(\w+)=(\d+)=(\d+)	3,{=},1,{=} ,2	5678=abc=1234	Change the order of the groups.

Language Analysis

This section contains information about tokenizers and filters related to character set conversion or for use with specific languages. For the European languages, tokenization is fairly straightforward. Tokens are delimited by whitespace and/or a relatively small set of punctuation characters. In other languages the tokenization rules are often not so simple. Some European languages may require special tokenization rules as well, such as rules for decompounding German words.

For more information about Solr's Language Analysis capabilities, see <https://wiki.apache.org/solr/LanguageAnalysis>.

Topics discussed in this section:

- [KeywordMarkerFilterFactory](#)
- [StemmerOverrideFilterFactory](#)
- [Dictionary Compound Word Token Filter](#)
- [Unicode Collation](#)
- [ISO Latin Accent Filter](#)

- [Russian](#)
- [Spanish](#)
- [Swedish](#)
- [Thai](#)
- [Turkish](#)

KeywordMarkerFilterFactory

Protects words from being modified by stemmers. A customized protected word list may be specified with the "protected" attribute in the schema. Any words in the protected word list will not be modified by any stemmer in Solr.

A sample Solr `protwords.txt` with comments can be found in the `/solr/conf/` directory:

```
<fieldtype name="myfieldtype" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.WhitespaceTokenizerFactory"/>
    <filter class="solr.KeywordMarkerFilterFactory" protected="protwords.txt" />
    <filter class="solr.PorterStemFilterFactory" />
  </analyzer>
</fieldtype>
```

StemmerOverrideFilterFactory

Overrides stemming algorithms by applying a custom mapping, then protecting these terms from being modified by stemmers.

A customized mapping of words to stems, in a tab-separated file, can be specified to the "dictionary" attribute in the schema. Words in this mapping will be stemmed to the stems from the file, and will not be further changed by any stemmer.

A sample [stemdict.txt](#) with comments can be found in the Source Repository.

```
<fieldtype name="myfieldtype" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.WhitespaceTokenizerFactory"/>
    <filter class="solr.StemmerOverrideFilterFactory" dictionary="stemdict.txt" />
    <filter class="solr.PorterStemFilterFactory" />
  </analyzer>
</fieldtype>
```

Dictionary Compound Word Token Filter

This filter splits, or *decompounds*, compound words into individual words using a dictionary of the component words. Each input token is passed through unchanged. If it can also be decompounded into subwords, each subword is also added to the stream at the same logical position.

Compound words are most commonly found in Germanic languages.

Factory class: `solr.DictionaryCompoundWordTokenFilterFactory`

Arguments:

dictionary: (required) The path of a file that contains a list of simple words, one per line. Blank lines and lines that begin with "#" are ignored. This path may be an absolute path, or path relative to the Solr config directory.

`minWordSize`: (integer, default 5) Any token shorter than this is not decomposed.

`minSubwordSize`: (integer, default 2) Subwords shorter than this are not emitted as tokens.

`maxSubwordSize`: (integer, default 15) Subwords longer than this are not emitted as tokens.

`onlyLongestMatch`: (true/false) If true (the default), only the longest matching subwords will generate new tokens.

Example:

Assume that `germanwords.txt` contains at least the following words:

`dummkopfdonaudampfschiff`

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.DictionaryCompoundWordTokenFilterFactory"
dictionary="germanwords.txt"/>
</analyzer>
```

In: "Donaudampfschiff dummkopf"

Tokenizer to Filter: "Donaudampfschiff"(1), "dummkopf"(2),

Out: "Donaudampfschiff"(1), "Donau"(1), "dampf"(1), "schiff"(1), "dummkopf"(2), "dumm"(2), "kopf"(2)

Unicode Collation

Unicode Collation is a language-sensitive method of sorting text that also be used for advanced search purposes.

Unicode Collation in Solr is fast, because all the work is done at index time. It uses a `KeywordTokenizerFactory` to create a sort field, followed by `CollationKeyFilterFactory`. The `CollationKeyFilterFactory` adds "sort keys" to the `sort` field at index time, so that at query time you can sort on the `sort` field and your results comes back in collated order.

Sorting Text for a Specific Language

In this example, text is sorted according to the default German rules provided by Java. The rules for sorting German in Java are defined in a package called a Java Locale.

Locales are typically defined as a combination of language and country, but you can specify just the language if you want. For example, if you specify "de" as the language, you will get sorting that works well for German language. If you specify "de" as the language and "CH" as the country, you will get German sorting specifically tailored for Switzerland.

You can see a list of supported Locales [here](#).

```
<!-- define a field type for German collation -->
<fieldType name="collatedGERMAN" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.KeywordTokenizerFactory"/>
    <filter class="solr.CollationKeyFilterFactory"
      language="de"
      strength="primary"
    />
  </analyzer>
</fieldType>
...
<!-- define a field to store the German collated manufacturer names -->
<field name="manuGERMAN" type="collatedGERMAN" indexed="true" stored="false" />
...
<!-- copy the text to this field. we could create French, English, Spanish versions
too,
and sort differently for different users! -->
<copyField source="manu" dest="manuGERMAN"/>
```

In the example above, we defined the strength as "primary". The strength of the collation determines how strict the sort order will be, but it also depends upon the language. For example, in English, "primary" strength ignores differences in case and accents.

For more information, see the [Collator javadocs](#).

Sorting Text for Multiple Languages

There are two approaches to supporting multiple languages: if there is a small list of languages you wish to support, consider defining collated fields for each language and using `copyField`. However, adding a large number of sort fields can increase disk and indexing costs. An alternative approach is to use the Unicode `default` collator.

The Unicode `default` or `ROOT` locale has rules that are designed to work well for most languages. To use the `default` locale, simply define the language as the empty string. This Unicode default sort is still significantly more advanced than the standard Solr sort.

```
<fieldType name="collatedROOT" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.KeywordTokenizerFactory"/>
    <filter class="solr.CollationKeyFilterFactory"
      language=""
      strength="primary"
    />
  </analyzer>
</fieldType>
```

Sorting Text with Custom Rules

You can define your own set of sorting rules. Its easiest to take existing rules that are close to what you want and customize them.

In the example below, we create a custom rule set for German called DIN 5007-2. This rule set treats umlauts in German differently: it treats ö as equivalent to oe. For more information, see the [RuleBasedCollator javadocs](#).

This example shows how to create a custom rule set and dump it to a file:

```
// get the default rules for Germany
// these are called DIN 5007-1 sorting
RuleBasedCollator baseCollator = (RuleBasedCollator) Collator.getInstance(new
Locale("de", "DE"));

// define some tailorings, to make it DIN 5007-2 sorting.
// For example, this makes ö equivalent to oe
String DIN5007_2_tailorings =
"& ae , a\u0308 & AE , A\u0308"+
"& oe , o\u0308 & OE , O\u0308"+
"& ue , u\u0308 & UE , u\u0308";

// concatenate the default rules to the tailorings, and dump it to a String
RuleBasedCollator tailoredCollator = new RuleBasedCollator(baseCollator.getRules() +
DIN5007_2_tailorings);
String tailoredRules = tailoredCollator.getRules();
// write these to a file, be sure to use UTF-8 encoding!!!
IOUtils.write(tailoredRules, new FileOutputStream("/solr_home/conf/customRules.dat"),
"UTF-8");
```

This rule set can now be used for custom collation in Solr:

```
<fieldType name="collatedCUSTOM" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.KeywordTokenizerFactory"/>
    <filter class="solr.CollationKeyFilterFactory"
      custom="customRules.dat"
      strength="primary"
    />
  </analyzer>
</fieldType>
```

Searching

Collation can also be used to search on a tokenized field.

In this example, we use the same custom German rules defined above on a tokenized field. As with stemmers, although the output tokens are nonsense they are the same values and will match for search purposes.

```
<fieldType name="collatedCUSTOM" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.CollationKeyFilterFactory"
      custom="customRules.dat"
      strength="primary"
    />
  </analyzer>
</fieldType>
```

ICU Collation

For better performance, less memory usage, and support for more locales, you can add the `analysis-extras` contrib and use `ICUCollationKeyFilterFactory` instead. See the [javadocs](#) for more information.

The principles of ICU Collation are the same as those of Unicode Collation; you just specify an RFC3066 language identifier with the locale parameter instead of specifying `language+country+variant`.

For example, to get German phonebook sort order:

```
<fieldType name="collatedICU" class="solr.TextField">
  <analyzer>
    <tokenizer class="solr.KeywordTokenizerFactory"/>
    <filter class="solr.ICUCollationKeyFilterFactory"
      locale="de@collation=phonebook"
      strength="primary"
    />
  </analyzer>
</fieldType>
```

To use the `ICUCollationKeyFilterFactory` filter, see `solr/contrib/analysis-extras/README.txt` for instructions on which jars you need to add to your `SOLR_HOME/lib`.

ISO Latin Accent Filter

This filter replaces any accented characters in a token with the unaccented equivalent. This can increase recall by causing more matches. On the other hand, it can reduce precision because language-specific character differences may be lost.

Characters in the ISO Latin 1 (ISO-8859-1) character set are recognized and letter case will be preserved, so that "Â" becomes "A" and "á" becomes "a".

 This filter only looks for accented characters, it does not filter out other non-ASCII characters.

Factory class: `solr.ISOLatin1AccentFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ISOLatin1AccentFilterFactory"/>
</analyzer>
```

In: "Björn Ångström"

Tokenizer to Filter: "Björn", "Ångström"

Out: "Bjorn", "Angstrom"

Arabic

Solr provides support for the [Light-10 \(PDF\)](#) stemming algorithm, and Lucene includes an example stopword list.

This algorithm defines both character normalization and stemming, so these are split into two filters to provide more flexibility.

Factory classes: `solr.ArabicStemFilterFactory`, `solr.ArabicNormalizationFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.ArabicNormalizationFilterFactory"/>
  <filter class="solr.ArabicStemFilterFactory"/>
</analyzer>
```

In: لوتقم

Tokenizer to Filter: لوتق, لتق

Out: لتق لتق

Brazilian Portuguese

This is a Java filter written specifically for stemming the Brazilian dialect of the Portuguese language. It uses the Lucene class `org.apache.lucene.analysis.br.BrazilianStemmer`. Although that stemmer can be configured to use a list of protected words (which should not be stemmed), this factory does not accept any arguments to specify such a list.

Factory class: `solr.BrazilianStemFilterFactory`

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.BrazilianStemFilterFactory"/>
</analyzer>
```

In: "praia praias"

Tokenizer to Filter: "praia", "praias"

Out: "pra", "pra"

Bulgarian

Solr includes a light stemmer for Bulgarian, following [this algorithm](#) (PDF), and Lucene includes an example stopwords list.

Factory class: solr.BulgarianStemFilterFactory

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.BulgarianStemFilterFactory"/>
</analyzer>
```

In: "вания ване ването"

Tokenizer to Filter: "вания", "ване", "ването"

Out: "ван", "ван", "ван"

Chinese

Chinese Tokenizer

The Chinese Tokenizer is deprecated as of Solr 3.4. Use the [solr.StandardTokenizerFactory](#) instead.

Factory class: solr.ChineseTokenizerFactory

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.ChineseTokenizerFactory"/>
</analyzer>
```

In: "你好，我不讲中文"

Out: "你", "好", "我", "不", "讲", "中", "文"

Chinese Filter Factory

The Chinese Filter Factory is deprecated as of Solr 3.4. Use the [solr.StopFilterFactory](#) instead.

Factory class: solr.ChineseFilterFactory

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ChineseFilterFactory"/>
</analyzer>
```

In: "你好, and 我不讲中文"

Tokenizer to Filter: "你", "好", "and", "我", "不", "讲", "中", "文"

Out: "你", "好", "我", "不", "讲", "中", "文"

Simplified Chinese

For Simplified Chinese, Solr provides support for Chinese sentence and word segmentation with the `solr.SmartChineseSentenceTokenFilterFactory` and `solr.SmartChineseWordTokenFilterFactory` in the `analysis-extras` contrib module. This component includes a large dictionary and segments Chinese text into words with the Hidden Markov Model. To use this filter, see `solr/contrib/analysis-extras/README.txt` for instructions on which jars you need to add to your `solr_home/lib`.

Factory class: solr.SmartChineseWordTokenFilterFactory

Arguments: None

Examples:

To use the default setup with fallback to English Porter stemmer for english words, use:

```
<analyzer class="org.apache.lucene.analysis.cn.smart.SmartChineseAnalyzer"/>
```

Or to configure your own analysis setup, use the `SmartChineseSentenceTokenizerFactory` along with your custom filter setup. The sentence tokenizer tokenizes on sentence boundaries and the `SmartChineseWordTokenFilter` breaks this further up into words.

```
<analyzer>
  <tokenizer class="solr.SmartChineseSentenceTokenizerFactory" />
  <filter class="solr.SmartChineseWordTokenFilterFactory" />
  <filter class="solr.LowerCaseFilterFactory" />
  <filter class="solr.PositionFilterFactory" />
</analyzer>
```

CJK

This tokenizer breaks Chinese, Japanese and Korean language text into tokens. These are not whitespace delimited languages. The tokens generated by this tokenizer are "doubles", overlapping pairs of CJK characters found in the field text.

Factory class: solr.CJKTokenizerFactory

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.CJKTokenizerFactory" />
</analyzer>
```

In: "你好，我不讲中文"

Out: "你好", "我不", "不讲", "讲中", "讲", "中文", ""

Czech

Solr includes a light stemmer for Czech, following [this algorithm](#), and Lucene includes an example stopwords list.

Factory class: solr.CzechStemFilterFactory

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory" />
  <filter class="solr.CzechStemFilterFactory" />
</analyzer>
```

In: "prezidenští, prezidenta, prezidentského"

Tokenizer to Filter: "prezidenští", "prezidenta", "prezidentského"

Out: "preziden", "preziden", "preziden"

Dutch

This is a Java filter written specifically for stemming the Dutch language. It uses the Lucene class `org.apache.lucene.analysis.nl.DutchStemmer`. Although that stemmer can be configured to use a list of protected words (which should not be stemmed), this factory does not accept any arguments to specify such a list.

Another option for stemming Dutch words is to use the Snowball Porter Stemmer with an argument of `language="Dutch"`.

Factory class: `solr.DutchStemFilterFactory`

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory" />
  <filter class="solr.DutchStemFilterFactory" />
</analyzer>
```

In: "kanaal kanalen"

Tokenizer to Filter: "kanaal", "kanalen"

Out: "kanal", "kanal"

Finnish

Solr includes support for stemming Finnish, and Lucene includes an example stopword list.

Factory class: `solr.FinnishLightStemFilterFactory`

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory" />
  <filter class="solr.FinnishLightStemFilterFactory" />
</analyzer>
```

In: "kala kalat"

Tokenizer to Filter: "kala", "kalat"

Out: "kala", "kala"

French

Elision Filter

Removes article elisions from a token stream. This filter primarily applies to the French language and makes use of the `ElisionFilter` class in `org.apache.lucene.analysis.fr`.

Factory class: `solr.ElisionFilterFactory`

Arguments:

articles: (required) The pathname of a file that contains a list of articles, one per line, to be stripped. Articles are words such as "le", which are commonly abbreviated, such as *l'avion* (the plane). This file should include the abbreviated form, which precedes the apostrophe. In this case, simply "/".

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ElisionFilterFactory"/>
</analyzer>
```

In: "L'histoire d'art"

Tokenizer to Filter: "L'histoire", "d'art"

Out: "histoire", "art"

French Light Stem Filter

Solr includes three stemmers for French: one in the `solr.SnowballPorterFilterFactory`, a lighter stemmer called `solr.FrenchLightStemFilterFactory`, and an even less aggressive stemmer called `solr.FrenchMinimalStemFilterFactory`. Lucene includes an example stopword list.

Factory classes: `solr.FrenchLightStemFilterFactory`, `solr.FrenchMinimalStemFilterFactory`

Arguments: None

Examples:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.ElisionFilterFactory"/>
  <filter class="solr.FrenchLightStemFilterFactory"/>
</analyzer>
```

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.ElisionFilterFactory"/>
  <filter class="solr.FrenchMinimalStemFilterFactory"/>
</analyzer>
```

In: "le chat, les chats"

Tokenizer to Filter: "le", "chat", "les", "chats"

Out: "le", "chat", "le", "chat"

Galician

Solr includes a stemmer for Galician following [this algorithm](#), and Lucene includes an example stopword list.

Factory class: solr.GalicianStemFilterFactory

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.GalicianStemFilterFactory"/>
</analyzer>
```

In: "felizmente Luzes"

Tokenizer to Filter: "felizmente", "luzes"

Out: "feliz", "luz"

German

Solr includes four stemmers for German: one in the `solr.SnowballPorterFilterFactory` `language="German"`, a stemmer called `solr.GermanStemFilterFactory`, a lighter stemmer called `solr.GermanLightStemFilterFactory`, and an even less aggressive stemmer called `solr.GermanMinimalStemFilterFactory`. Lucene includes an example stopwords list.

Factory classes: `solr.GermanStemFilterFactory`, `solr.LightGermanStemFilterFactory`, `solr.MinimalGermanStemFilterFactory`

Arguments: None

Examples:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory "/>
  <filter class="solr.GermanStemFilterFactory"/>
</analyzer>
```

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory "/>
  <filter class="solr.GermanLightStemFilterFactory"/>
</analyzer>
```

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory "/>
  <filter class="solr.GermanMinimalStemFilterFactory"/>
</analyzer>
```

In: "hund hunden"

Tokenizer to Filter: "hund", "hunden"

Out: "hund", "hund"

Greek

This filter converts uppercase letters in the Greek character set to the equivalent lowercase character.

Factory class: `solr.GreekLowerCaseFilterFactory`

Arguments:

`charset`: (optional, default "UnicodeGreek") Specifies the name of the character set to use. Must be "UnicodeGreek", "ISO" or "CP1253".

 Use of custom charsets was deprecated in Solr 1.4 and is unsupported in Solr 3.1. If you need to index text in these encodings, please use Java's character set conversion facilities (InputStreamReader, and so on.) during I/O, so that Lucene can analyze this text as Unicode instead.

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.GreekLowerCaseFilterFactory"/>
</analyzer>
```

In: "Ελληνική Δημοκρατία Ellīnikī Dīmokratía"

Tokenizer to Filter: "Ελληνική", "Δημοκρατία", "Ellīnikī", "Dīmokratía"

Out: "ελληνικη", "δημοκρατια", "ellīnikī", "dīmokratía"

Hindi

Solr includes support for stemming Hindi following [this algorithm](#) (PDF), support for common spelling differences through the `solr.HindiNormalizationFilterFactory` following [this algorithm](#) (PDF), support for encoding differences through the `solr.IndicNormalizationFilterFactory` following [this algorithm](#), and Lucene includes an example stopwords list.

Factory classes: `solr.IndicNormalizationFilterFactory`, `solr.HindiNormalizationFilterFactory`, `solr.HindiStemFilterFactory`

Arguments: None

Example:

```
<filter class="solr.IndicNormalizationFilterFactory"/>
  <filter class="solr.HindiNormalizationFilterFactory"/>
  <filter class="solr.HindiStemFilterFactory"/>
```

In: "बैबहना गुसपेतयोम"

Out: "बैबहन", "गुसपेट"

Indonesian

Solr includes support for stemming Indonesian (Bahasa Indonesia) following [this algorithm](#) (PDF), and Lucene includes an example stopwords list.

Factory class: `solr.IndonesianStemFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory" />
  <filter class="solr.IndonesianStemFilterFactory" stemDerivational="true" />
</analyzer>
```

In: "sebagai sebagainya"

Tokenizer to Filter: "sebagai", "sebagainya"

Out: "bagai", "bagai"

Italian

Solr includes two stemmers for Italian: one in the `solr.SnowballPorterFilterFactory` `language="Italian"`, and a lighter stemmer called `solr.ItalianLightStemFilterFactory`. Lucene includes an example stopwords list.

Factory class: `solr.ItalianStemFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory" />
  <filter class="solr.ItalianLightStemFilterFactory" />
</analyzer>
```

In: "propaga propagare propagamento"

Tokenizer to Filter: "propaga", "propagare", "propagamento"

Out: "propag", "propag", "propag"

Lao, Myanmar, Khmer

Lucene provides support for segmenting these languages into syllables with the `solr.ICUTokenizerFactory` in the `analysis-extras` contrib module. To use this tokenizer, see `solr/contrib/analysis-extras/README.txt` for instructions on which jars you need to add to your `solr_home/lib`.

Latvian

Solr includes support for stemming Latvian, and Lucene includes an example stopwords list.

Factory class: `solr.LatvianStemFilterFactory`

Arguments: None

Example:

```
<fieldType name="text_lvstem" class="solr.TextField" positionIncrementGap="100">
  <analyzer>
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
    <filter class="solr.LatvianStemFilterFactory"/>
  </analyzer>
</fieldType>
```

In: "tirgiem tirgus"

Tokenizer to Filter: "tirgiem", "tirgus"

Out: "tirg", "tirg"

Persian

Persian Filter Factories

Solr includes support for normalizing Persian, and Lucene includes an example stopwords list.

Factory class: `solr.PersianNormalizationFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.ArabicNormalizationFilterFactory"/>
  <filter class="solr.PersianNormalizationFilterFactory"/>
</analyzer>
```

In: "اه گرب اه گرب"

Tokenizer to Filter: "اه گرب", "اه گرب"

Out: "گرب", "گرب"

Polish

Lucene provides support for Polish stemming with the `solr.StempelPolishStemFilterFactory` in the `contrib/analysis-extras` module. This component includes an algorithmic stemmer with tables for Polish. To use this filter, see `solr/contrib/analysis-extras/README.txt` for instructions on which jars you need to add to your `solr_home/lib`.

Factory class: `solr.StempelPolishStemFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory" />
  <filter class="solr.solr.StempelPolishStemFilterFactory" />
</analyzer>
```

In: ""studenta studenci"

Tokenizer to Filter: "studenta", "studenci"

Out: "student", "student"

Portuguese

Solr includes four stemmers for Portuguese: one in the `solr.SnowballPorterFilterFactory`, an alternative stemmer called `solr.PortugueseStemFilterFactory`, a lighter stemmer called `solr.PortugueseLightStemFilterFactory`, and an even less aggressive stemmer called `solr.PortugueseMinimalStemFilterFactory`. Lucene includes an example stopword list.

Factory class: `solr.PortugueseStemFilterFactory`, `solr.PortugueseLightStemFilterFactory`, `solr.PortugueseMinimalStemFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.PortugueseStemFilterFactory"/>
</analyzer>
```

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.PortugueseLightStemFilterFactory"/>
</analyzer>
```

```
<analyzer>
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.LowerCaseFilterFactory"/>
  <filter class="solr.PortugueseMinimalStemFilterFactory"/>
</analyzer>
```

In: "praia praias"

Tokenizer to Filter: "praia", "praias"

Out: "pra", "pra"

Russian

Russian Letter Tokenizer

This tokenizer breaks Russian language text into tokens. It is similar to LetterTokenizer, but additionally looks up letters in the appropriate Russian character set.

Factory class: solr.RussianLetterTokenizerFactory

Arguments:

charset: (optional, default "UnicodeRussian") The name of the character set to use. Must be "UnicodeRussian", "KOI8" or "CP1251".

Use of custom charsets was deprecated in Solr 1.4 and is unsupported in Solr 3.1. If you need to index text in these encodings, please use Java's character set conversion facilities (InputStreamReader, and so on.) during I/O, so that Lucene can analyze this text as Unicode instead.

Example:

```
<analyzer type="index">
  <tokenizer class="solr.RussianLetterTokenizerFactory"/>
</analyzer>
```

In: "Здравствулте!. Я не говорю русского."

Out: "Здравствулте", "Я", "не", "говорю", "русского"

Russian Lower Case Filter

This filter converts uppercase letters in the Russian character set to the equivalent lowercase character.

Factory class: solr.RussianLowerCaseFilterFactory

Arguments:

charset: (optional, default "UnicodeRussian") Specifies the name of the character set to use. Must be "UnicodeRussian", "KOI8" or "CP1251".

Use of custom charsets was deprecated in Solr 1.4 and is unsupported in Solr 3.1. If you need to index text in these encodings, please use Java's character set conversion facilities (InputStreamReader, and so on.) during I/O, so that Lucene can analyze this text as Unicode instead.

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.RussianLowerCaseFilterFactory"/>
</analyzer>
```

In: "Здравствулте!. Я не говорю русского."

Tokenizer to Filter: "Здравствулте", "Я", "не", "говорю", "русского"

Out: "здравствулте", "я", "не", "говорю", "русского"

Russian Stem Filter

Solr includes two stemmers for Russian: one in the `solr.SnowballPorterFilterFactory` `language="Russian"`, and a lighter stemmer called `solr.RussianLightStemFilterFactory`. Lucene includes an example stopword list.

Factory class: `solr.RussianLightStemFilterFactory`

Arguments:

`charset`: (optional, default "UnicodeRussian") Specifies the name of the character set to use. Must be "UnicodeRussian", "KOI8" or "CP1251".

Use of custom charsets was deprecated in Solr 1.4 and is unsupported in Solr 3.4. If you need to index text in these encodings, please use Java's character set conversion facilities (`InputStreamReader`, and so on.) during I/O, so that Lucene can analyze this text as Unicode instead.

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.RussianLowerCaseFilterFactory"/>
  <filter class="solr.RussianLightStemFilterFactory"/>
</analyzer>
```

In: "вал валы"

Tokenizer to Filter: "вал", "валы"

Out: "вал", "вал"

Spanish

Solr includes two stemmers for Spanish: one in the `solr.SnowballPorterFilterFactory` `language="Spanish"`, and a lighter stemmer called `solr.SpanishLightStemFilterFactory`. Lucene includes an example stopword list.

Factory class: `solr.SpanishStemFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory" />
  <filter class="solr.SpanishLightStemFilterFactory" />
</analyzer>
```

In: "torear toreara torearlo"

Tokenizer to Filter: "torear", "toreara", "torearlo"

Out: "tor", "tor", "tor"

Swedish

Swedish Stem Filter

Solr includes two stemmers for Swedish: one in the `solr.SnowballPorterFilterFactory` `language="Swedish"`, and a lighter stemmer called `solr.SwedishLightStemFilterFactory`. Lucene includes an example stopword list.

Factory class: `solr.SwedishStemFilterFactory`

Arguments: None

Example:

```
<analyzer>
  <filter class="solr.LowerCaseFilterFactory" />
  <filter class="solr.SwedishLightStemFilterFactory" />
</analyzer>
```

In: "kloke klokhet klokheten"

Tokenizer to Filter: "kloke", "klokhet", "klokheten"

Out: "klok", "klok", "klok"

Thai

This filter converts sequences of Thai characters into individual Thai words. Unlike European languages, Thai does not use whitespace to delimit words.

Factory class: `solr.ThaiWordFilterFactory`

Arguments: None

Example:

```
<analyzer type="index">
  <tokenizer class="solr.StandardTokenizerFactory"/>
  <filter class="solr.ThaiWordFilterFactory"/>
</analyzer>
```

In: "ข้างลิบสามเชือก"

Tokenizer to Filter: "ข้างลิบสามเชือก"

Out: "ข้าง", "ลิบ", "สาม", "เชือก"

Turkish

Solr includes support for stemming Turkish through the `solr.SnowballPorterFilterFactory`, as well as support for case-insensitive search through the `solr.TurkishLowerCaseFilterFactory`, and Lucene includes an example stopwords list.

Factory class: `solr.TurkishLowerCaseFilterFactory`

Arguments: None

Example:

```
<filter class="solr.TurkishLowerCaseFilterFactory"/>
  <filter class="solr.SnowballPorterFilterFactory" language="Turkish" />
```

Running Your Analyzer

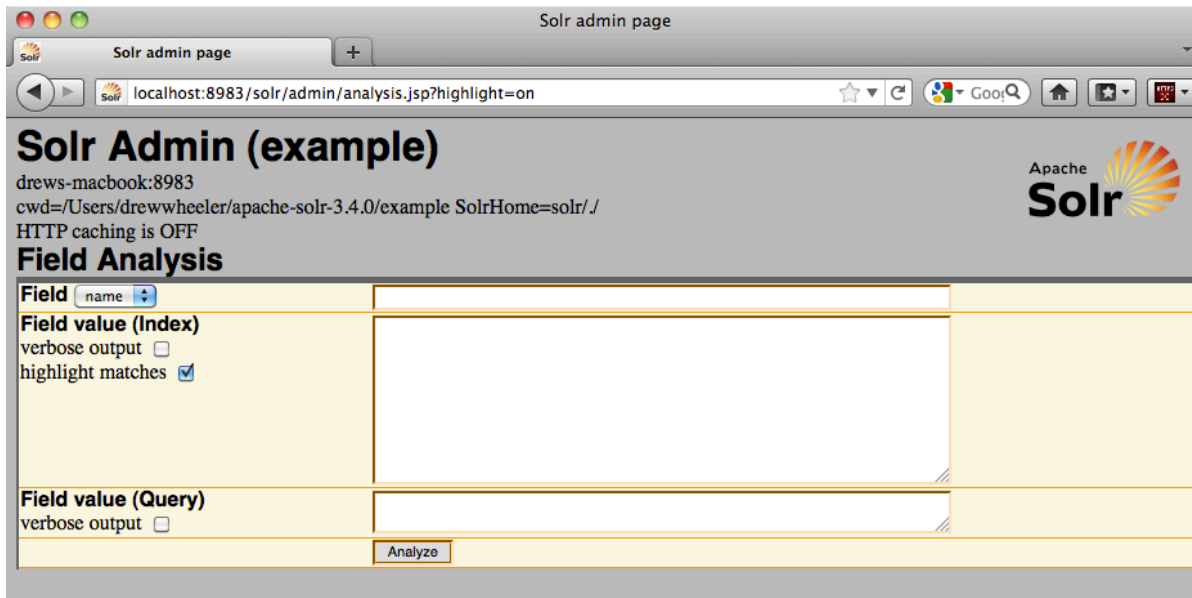

Once you've defined a field type in `schema.xml` and specified the analysis steps that you want applied to it, you should test it out to make sure that it behaves the way you expect it to. Luckily, there is a very handy page in the Solr [admin interface](#) that lets you do just that. You can invoke the analyzer for any text field, provide sample input, and display the resulting token stream.

For example, assume that the following field type definition has been added to `schema.xml`:

```
<fieldType name="mytextfield" class="solr.TextField">
  <analyzer type="index">
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.HyphenatedWordsFilterFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
  </analyzer>  <analyzer type="query">
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
  </analyzer>
</fieldType>
```

The objective here (during indexing) is to reconstruct hyphenated words, which may have been split across lines in the text, then to set all words to lowercase. For queries, you want to skip the de-hyphenation step.

To test this out, point your browser at the Field Analysis page of the [Solr Admin Web interface](#). By default, this will be at the following URL (adjust the hostname and/or port to match your configuration): <http://localhost:8983/solr/admin/analysis.jsp>. You should see a page like this.

Empty Field Analysis screen.

We want to test the field type definition for "mytextfield", defined above. The drop-down labeled "Field" has two values, "name" and "type". Choosing "type" allows you to give the value of the name attribute in a `<fieldType>` definition, "mytextfield" for this example.

You can also select "name" and provide the name of a `<field>` definition from `schema.xml`. A field definition refers to a type definition, so this is essentially an indirect way of the selecting the field's type.

In the "Field Value" box enter some sample text to be processed by the analyzer. The results of each analysis stage will be displayed when you click the **Analyze** button. Let's test the index analyzer by providing some sample text. We will leave the query field value empty for now. The result we expect is that `HyphenatedWordsFilter` will join the hyphenated pair "Super-" and "computer" into the single word "Supercomputer", and then `LowerCaseFilter` will set it to "supercomputer". Let's see what happens:

Solr Admin (example)
 localhost:8983
 cwd=/Users/drewwheeler/apache-solr-3.4.0/example SolrHome=solr/
 HTTP caching is OFF

Field Analysis

Field type: mytextfield

Field value (Index)
 Super-computer

Field value (Query)

Analyze

Index Analyzer
 org.apache.solr.analysis.StandardTokenizerFactory {luceneMatchVersion=LUCENE_34}

position	1	2
term text	Super-	computer
startOffset	0	8
endOffset	5	16
type	<ALPHANUM>	<ALPHANUM>

org.apache.solr.analysis.HyphenatedWordsFilterFactory {luceneMatchVersion=LUCENE_34}

position	1	2
term text	Super	computer
startOffset	0	8
endOffset	5	16
type	<ALPHANUM>	<ALPHANUM>

org.apache.solr.analysis.LowerCaseFilterFactory {luceneMatchVersion=LUCENE_34}

position	1	2
term text	super	computer
startOffset	0	8
endOffset	5	16
type	<ALPHANUM>	<ALPHANUM>

Running index-time analyzer, verbose output.

The result is two distinct tokens rather than the one we expected. What went wrong? Looking at the first token that came out of `StandardTokenizer`, we can see the trailing hyphen has been stripped off of "Super-". Checking the documentation for `StandardTokenizer`, we see that it treats all punctuation characters as delimiters and discards them. What we really want in this case is a whitespace tokenizer that will preserve the hyphen character when it breaks the text into tokens.

Let's make this change and try again:

```
<fieldType name="mytextfield" class="solr.TextField">
  <analyzer type="index">
    <tokenizer class="solr.WhitespaceTokenizerFactory"/>
    <filter class="solr.HyphenatedWordsFilterFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
  </analyzer>
  <analyzer type="query">
    <tokenizer class="solr.StandardTokenizerFactory"/>
    <filter class="solr.LowerCaseFilterFactory"/>
  </analyzer>
</fieldType>
```

The screenshot shows the Solr Admin web interface. At the top, it says "Solr Admin (example)" and "localhost:8983". The Apache Solr logo is in the top right. The main section is titled "Field Analysis". It shows a form where the field name is "mytextfield" and the field value (Index) is "Super-computer". There are checkboxes for "verbose output" and "highlight matches", both of which are checked. Below the form is an "Analyze" button. Underneath the form, there are three sections for the Index Analyzer, each showing a table of results for a different filter factory:

org.apache.solr.analysis.WhitespaceTokenizerFactory {luceneMatchVersion=LUCENE_34}

position	1	2
term text	Super-	computer
startOffset	0	8
endOffset	6	16

org.apache.solr.analysis.HyphenatedWordsFilterFactory {luceneMatchVersion=LUCENE_34}

position	1
term text	Supercomputer
startOffset	0
endOffset	16

org.apache.solr.analysis.LowerCaseFilterFactory {luceneMatchVersion=LUCENE_34}

position	1
term text	supercomputer
startOffset	0
endOffset	16

Using WhitespaceTokenizer, expected results.

Re-submitting the form by clicking "Analyze" again, we see the result in the screen shot above.

That's more like it. Because the whitespace tokenizer preserved the trailing hyphen on the first token, `HyphenatedWordsFilter` was able to reconstruct the hyphenated word, which then passed it on to `LowerCaseFilter`, where capital letters are set to lowercase.

Now let's see what happens when invoking the analyzer for query processing. For query terms, we don't want to do de-hyphenation and we *do* want to discard punctuation, so let's try the same input on it. We'll copy the same text to the "Field value (Query)" box and clear the one for index analysis. We'll also include the full, unhyphenated word as another term to make sure it is processed to lower case as we expect. Submitting again yields these results:

Solr Admin (example)
 localhost:8983
 cwd=/Users/drewwheeler/apache-solr-3.4.0/example SolrHome=solr/
 HTTP caching is OFF

Field Analysis

Field type: mytextfield

Field value (Index):
 verbose output
 highlight matches

Field value (Query): Super-computer Supercomputer
 verbose output

Analyze

Query Analyzer
 org.apache.solr.analysis.StandardTokenizerFactory {luceneMatchVersion=LUCENE_34}

position	1	2	3
term text	Super	computer	Supercomputer
startOffset	0	6	15
endOffset	5	14	28
type	<ALPHANUM>	<ALPHANUM>	<ALPHANUM>

org.apache.solr.analysis.LowerCaseFilterFactory {luceneMatchVersion=LUCENE_34}

position	1	2	3
term text	super	computer	supercomputer
startOffset	0	6	15
endOffset	5	14	28
type	<ALPHANUM>	<ALPHANUM>	<ALPHANUM>

Query-time analyzer, good results.

We can see that for queries the analyzer behaves the way we want it to. Punctuation is stripped out, `HyphenatedWordsFilter` doesn't run, and we wind up with the three tokens we expected.

Refer to the section [Running Field Analysis to Test Analyzers, Tokenizers, and TokenFilters](#) for more information about conducting field analysis through the Admin Web interface.

Indexing and Basic Data Operations

This section describes how Solr adds data to its index. It covers the following topics:

[What Is Indexing?](#): An overview of Solr's indexing process.

[Uploading Data with Solr Cell using Apache Tika](#): Information about using the Solr Cell framework to upload data for indexing.

[Uploading Data with Index Handlers](#): Information about using Solr's Index Handlers to upload XML and CSV data.

[Uploading Structured Data Store Data with the Data Import Handler](#): Information about uploading and indexing data from a structured data store.

[UIMA Integration](#): Information about integrating Solr with Apache's Unstructured Information Management Architecture (UIMA). UIMA lets you define custom pipelines of Analysis Engines that incrementally add metadata to your documents as annotations.

[Content Streams](#): Information about streaming content to Solr Request Handlers.

What Is Indexing?

This section describes the process of indexing: adding content to a Solr index and, if necessary, modifying that content or deleting it. By adding content to an index, we make it searchable by Solr.

A Solr index can accept data from many different sources, including XML files, comma-separated value (CSV) files, data extracted from tables in a database, and files in common file formats such as Microsoft Word or PDF.

Here are the three most common ways of loading data into a Solr index:

- Using the [Solr Cell](#) framework built on Apache Tika for ingesting binary files or structured files such as Office, Word, PDF, and other proprietary formats.
- Uploading XML files by sending HTTP requests to the Solr server from any environment where such requests can be generated.
- Writing a custom Java application to ingest data through Solr's Java Client API (which is described in more detail in [Client APIs](#). See also the JavaDocs for the SolrJ API: <http://lucene.apache.org/solr/api/solrj/index.html>). Using the Java API may be the best choice if you're working with an application, such as a Content Management System (CMS), that offers a Java API.

Regardless of the method used to ingest data, there is a common basic data structure for data being fed into a Solr index: a *document* containing multiple *fields*, each with a *name* and containing *content*, which may be empty. One of the fields is usually designated as a unique ID field (analogous to a primary key in a database), although the use of a unique ID field is not strictly required by Solr.

If the field name is defined in the `schema.xml` file that is associated with the index, then the analysis steps associated with that field will be applied to its content when the content is tokenized. Fields that are not explicitly defined in the schema will either be ignored or mapped to a dynamic field definition (see [Documents, Fields, and Schema Design](#)), if one matching the field name exists.

For more information on indexing in Solr, see the [Solr Wiki](#).

The Solr 3.4 Example Directory

The `example/` directory in the Solr 3.4 release includes a sample Solr implementation, along with sample documents for uploading into an index. You will find the example docs in `solr_home/example/exampledocs`.

The curl Utility for Transferring Files

Many of the instructions and examples in this section make use of the `curl` utility for transferring content through a URL. `curl` posts and retrieves data over HTTP, FTP, and many other protocols. Most Linux distributions include a copy of `curl`. You'll find `curl` downloads for Linux, Windows, and many other operating systems at <http://curl.haxx.se/download.html>. Documentation for `curl` is available here: <http://curl.haxx.se/docs/manpage.html>.

 Using `curl` or other command line tools for posting data is just fine for examples or tests, but it's not the recommended method for achieving the best performance for updates in production environments. You'll achieve better performance with Solr Cell or the other methods described in this section.

Instead of `curl`, you can use utilities such as GNU `wget` (<http://www.gnu.org/software/wget/>) or manage GETs and POSTS with Perl, although the command line options will differ.

Uploading Data with Solr Cell using Apache Tika

Earlier releases of Solr could easily index data that was already in XML format, but indexing non-XML data, such as binary files or Office documents, required extra processing. Solr 3.4 uses code from the [Apache Tika](#) project to provide a framework for incorporating many different file-format parsers such as [Apache PDFBox](#) and [Apache POI](#) into Solr itself. Working with this framework, Solr's `ExtractingRequestHandler` can use Tika to support uploading binary files—including files in popular formats such as Word and PDF—for data extraction and indexing.

When this framework was under development, it was called the Solr Content Extraction Library or CEL; from that abbreviation came this framework's name: Solr Cell.

For more information on Solr's Extracting Request Handler, see <https://wiki.apache.org/solr/ExtractingRequestHandler>.

Topics covered in this section:

- [Key Concepts](#)
- [Trying out Tika with the Solr Example Directory](#)
- [Input Parameters](#)
- [Order of Operations](#)
- [Configuring the Solr `ExtractingRequestHandler`](#)
- [Metadata](#)
- [Examples of Uploads Using the Extraction Request Handler](#)
- [Sending Documents to Solr with a POST](#)
- [Sending Documents to Solr with Solr Cell and SolrJ](#)

Key Concepts

When using the Solr Cell framework, it is helpful to keep the following in mind:

- Tika will automatically attempt to determine the input document type (Word, PDF, HTML) and extract the content appropriately. If you like, you can explicitly specify a MIME type for Tika with the `stream.type` parameter.
- Tika works by producing an XHTML stream that it feeds to a SAX ContentHandler. SAX is a common interface implemented for many different XML parsers. For more information, see <http://www.saxproject.org/quickstart.html>.
- Solr then responds to Tika's SAX events and creates the fields to index.

- Tika produces metadata such as Title, Subject, and Author according to specifications such as the DublinCore. See <http://lucene.apache.org/tika/formats.html> for the file types supported.
- Tika adds all the extracted text to the `content` field.
- You can map Tika's metadata fields to Solr fields. You can also boost these fields.
- You can pass in literals for field values.
- You can apply an XPath expression to the Tika XHTML to restrict the content that is produced.

Trying out Tika with the Solr Example Directory

You can try out the Tika framework using the example application included in the Solr 3.4 release. Start the Solr example server:

```
cd example -jar start.jar
```

In a separate window go to the `docs/` directory (which contains some nice example docs), or the `site` directory if you built Solr from source, and send Solr a file via HTTP POST:

```
cd docs
curl 'http://localhost:8983/solr/update/extract?literal.id=doc1&commit=true'
-F "myfile=@tutorial.html"
```

The URL above calls the Extraction Request Handler, uploads the file `tutorial.html` and assigns it the unique ID `doc1`. Here's a closer look at the components of this command:

- The `literal.id=doc1` parameter provides the necessary unique ID for the document being indexed.
- The `commit=true` parameter causes Solr to perform a commit after indexing the document, making it immediately searchable. For optimum performance when loading many documents, don't call the commit command until you are done.
- The `-F` flag instructs curl to POST data using the Content-Type `multipart/form-data` and supports the uploading of binary files. The `@` symbol instructs curl to upload the attached file.
- The argument `myfile=@tutorial.html` needs a valid path, which can be absolute or relative (for example, `myfile=@../../site/tutorial.html` if you are still in `exampledocs` directory).

Now you should be able to execute a query and find that document (open the following link in your browser): <http://localhost:8983/solr/select?q=tutorial>.

You may notice that although you can search on any of the text in the sample document, you may not be able to see that text when the document is retrieved. This is simply because the "content" field generated by Tika is mapped to the Solr field called `text`, which is indexed but not stored. This operation is controlled by default map rule in the `/update/extract` handler in `solrconfig.xml`, and its behavior can be easily changed or overridden. For example, to store and see all metadata and content, execute the following:

```
curl
'http://localhost:8983/solr/update/extract?literal.id=doc1&uprefix=attr_&fmap.content=attr_
-F "myfile=@tutorial.html"
```

In this command, the `uprefix=attr_` parameter causes all generated fields that aren't defined in the schema to be prefixed with `attr_`, which is a dynamic field that is stored.

The `fmap.content=attr_content` parameter overrides the default `fmap.content=text` causing the content to be added to the `attr_content` field instead.

Then run this command to query the document:

http://localhost:8983/solr/select?q=attr_content:tutorial

Input Parameters

The table below describes the parameters accepted by the Extraction Request Handler.

Parameter	Description
<code>boost.<fieldname>=<float></code>	Boosts the specified field. (Boosting a field alters its importance in a query response. To learn about boosting fields, see Searching .)
<code>capture=<Tika_XHTML_name></code>	Captures XHTML elements with the specified name for a supplementary addition to the Solr document. This parameter can be useful for copying chunks of the XHTML into a separate field. For instance, it could be used to grab paragraphs (<code><p></code>) and index them into a separate field. Note that content is still also captured into the overall "content" field.
<code>captureAttr=true false</code>	Indexes attributes of the Tika XHTML elements into separate fields, named after the element. For example, when extracting from HTML, Tika can return the href attributes in <code><a></code> tags as fields named "a". See the examples below.
<code>commitWithin</code>	Add the document within the specified number of milliseconds.
<code>defaultField=<field_name></code>	If the <code>uprefix</code> parameter (see below) is not specified and a field cannot be determined, the default field will be used.

<code>extractOnly=true false</code>	Default is false. If true, returns the extracted content from Tika without indexing the document. This literally includes the extracted XHTML as a string in the response. When viewing manually, it may be useful to use a response format other than XML to aid in viewing the embedded XHTML tags. For an example, see http://wiki.apache.org/solr/TikaExtractOnlyExampleOutput .
<code>extractFormat=xml text</code>	Default is xml. Controls the serialization format of the extract content. The xml format is actually XHTML, the same format that results from passing the <code>-x</code> command to the Tika command line application, while the text format is like that produced by Tika's <code>-t</code> command. This parameter is valid only if <code>extractOnly</code> is set to true.
<code>fmap.<source_field>=<target_field></code>	Maps (moves) one field name to another. Example: <code>fmap.content=text</code> causes the content field generated by Tika to be moved to the "text" field.
<code>literal.<fieldname>=<value></code>	Creates a field with the specified value. The data can be multivalued if the field is multivalued.
<code>lowernames=true false</code>	Maps all field names to lowercase with underscores. For example, "Content-Type" would be mapped to "content_type."
<code>resource.name=<file_name></code>	Specifies the optional name of the file. Tika can use it as a hint for detecting a file's MIME type.
<code>uprefix=<prefix></code>	Prefixes all fields that are not defined in the schema with the given prefix. This is very useful when combined with dynamic field definitions. Example: <code>uprefix=ignored_</code> would effectively ignore all unknown fields generated by Tika given the example schema contains <code><dynamicField name="ignored_*" type="ignored"/></code>
<code>xpath=<XPath_expression></code>	When extracting, only return Tika XHTML content that satisfies the XPath expression. See http://lucene.apache.org/tika/documentation.html for details on the format of Tika XHTML. See also http://wiki.apache.org/solr/TikaExtractOnlyExampleOutput .

Order of Operations

Here is the order in which the Solr Cell framework, using the Extraction Request Handler and Tika, processes its input.

1. Tika generates fields or passes them in as literals specified by `literal.<fieldname>=<value>`.

2. If `lowernames=true`, Tika maps fields to lowercase.
3. Tika applies the mapping rules specified by `fmap`. `source = target` parameters.
4. If `uprefix` is specified, any unknown field names are prefixed with that value, else if `defaultField` is specified, any unknown fields are copied to the default field.

Configuring the Solr ExtractingRequestHandler

If you are not working in the supplied `example/solr` directory, you must copy all libraries from `example/solr/libs` into a `libs` directory within your own `solr` directory or to a directory you've specified in `solrconfig.xml` using the new `libs` directive. The `ExtractingRequestHandler` is not incorporated into the Solr WAR file, so you have to install it separately.

Here's an example of configuring the `ExtractingRequestHandler` in `solrconfig.xml`.

```
<requestHandler name="/update/extract"
class="org.apache.solr.handler.extraction.ExtractingRequestHandler">
  <lst name="defaults">
    <str name="fmap.Last-Modified">last_modified</str>
    <str name="uprefix">ignored_</str>
  </lst>
  <!--Optional. Specify a path to a tika configuration file. See the Tika docs for
details.-->
  <str name="tika.config">/my/path/to/tika.config</str>
  <!-- Optional. Specify one or more date formats to parse. See
DateUtil.DEFAULT_DATE_FORMATS
for default date formats -->
  <lst name="date.formats">
    <str>yyyy-MM-dd</str>
  </lst>
</requestHandler>
```

In the `defaults` section, we are mapping Tika's Last-Modified Metadata attribute to a field named `last_modified`. We are also telling it to ignore undeclared fields. These are all overridden parameters.

The `tika.config` entry points to a file containing a Tika configuration. You would only need this entry if you have customized your Tika configuration. The Tika configuration file contains information about parsers, MIME types, and so on.

You may also need to adjust the `multipartUploadLimitInKB` attribute as follows if you are submitting very large documents.

```
<requestDispatcher handleSelect="true" >
  <requestParsers enableRemoteStreaming="false" multipartUploadLimitInKB="20480" />
  ...
</requestDispatcher >
```

Lastly, the `date.formats` allows you to specify various `java.text.SimpleDateFormat` date formats for working with transforming extracted input to a `Date`. Solr comes configured with the following date formats (see the `DateUtil` in Solr):

```
yyyy-MM-dd'T'HH:mm:ss'Z'
yyyy-MM-dd'T'HH:mm:ss
yyyy-MM-dd
yyyy-MM-dd hh:mm:ss
yyyy-MM-dd HH:mm:ss
EEE MMM d hh:mm:ss z YYYY
EEE, dd MMM yyyy HH:mm:ss zzz
EEEE, dd-MMM-yy HH:mm:ss zzz
EEE MMM d HH:mm:ss YYYY
```

Multi-Core Configuration

For a multi-core configuration, specify `sharedLib='lib'` in `<solr/>` in `example/solr/solr.xml` in order for Solr to find the JAR files in `example/solr/lib`.

For more information about Solr cores, see [The Well-Configured Solr Instance](#).

Metadata

As mentioned before, Tika produces metadata about the document. Metadata describes different aspects of a document, such as the author's name, the number of pages, the file size, and so on. The metadata produced depends on the type of document submitted. For instance, PDFs have different metadata than Word documents do.

In addition to Tika's metadata, Solr adds the following metadata (defined in `ExtractingMetadataConstants`):

Solr Metadata	Description
<code>stream_name</code>	The name of the Content Stream as uploaded to Solr. Depending on how the file is uploaded, this may or may not be set
<code>stream_source_info</code>	Any source info about the stream. (See the section on Content Streams later in this section.)
<code>stream_size</code>	The size of the stream in bytes.

stream_content_type	The content type of the stream, if available.
---------------------	---

 We recommend that you try using the `extractOnly` option to discover which values Solr is setting for these metadata elements.

Examples of Uploads Using the Extraction Request Handler

Capture and Mapping

The command below captures `<div>` tags separately, and then maps all the instances of that field to a dynamic field named `foo_t`.

```
curl "http://localhost:8983/solr/update/extract?literal.id=doc2&captureAttr=true
&defaultField=text&fmap.div=foo_t&capture=div" -F "tutorial=@tutorial.pdf"
```

Capture, Mapping, and Boosting

The command below captures `<div>` tags separately, maps the field to a dynamic field named `foo_t`, then boosts `foo_t` by 3.

```
curl "http://localhost:8983/solr/update/extract?literal.id=doc3&captureAttr=true
&defaultField=text&capture=div&fmap.div=foo_t&boost.foo_t=3"
-F "tutorial=@tutorial.pdf"
```

Using Literals to Define Your Own Metadata

To add in your own metadata, pass in the `literal` parameter along with the file:

```
curl "http://localhost:8983/solr/update/extract?literal.id=doc4&captureAttr=true
&defaultField=text&capture=div&fmap.div=foo_t&boost.foo_t=3&literal.blah_s=Bah"
-F "tutorial=@tutorial.pdf"
```

XPath

The example below passes in an XPath expression to restrict the XHTML returned by Tika:

```
curl "http://localhost:8983/solr/update/extract?literal.id=doc5&captureAttr=true
&defaultField=text&capture=div&fmap.div=foo_t&boost.foo_t=3&literal.id=id
&xpath=/xhtml:html/xhtml:body/xhtml:div/descendant:node()"
-F "tutorial=@tutorial.pdf"
```

Extracting Data without Indexing It

Solr allows you to extract data without indexing. You might want to do this if you're using Solr solely as an extraction server or if you're interested in testing Solr extraction.

The example below sets the `extractOnly=true` parameter to extract data without indexing it.

```
curl "http://localhost:8983/solr/update/extract?&extractOnly=true"
--data-binary @tutorial.html
-H 'Content-type:text/html'
```

The output includes XML generated by Tika (and further escaped by Solr's XML) using a different output format to make it more readable:

```
curl "http://localhost:8983/solr/update/extract?&extractOnly=true&wt=ruby&indent=true"
--data-binary @tutorial.html
-H 'Content-type:text/html'
```

Sending Documents to Solr with a POST

The example below streams the file as the body of the POST, which does not, then, provide information to Solr about the name of the file.

```
curl "http://localhost:8983/solr/update/extract?literal.id=doc5&defaultField=text"
--data-binary @tutorial.html
-H 'Content-type:text/html'
```

Sending Documents to Solr with Solr Cell and SolrJ

SolrJ is a Java client that you can use to add documents to the index, update the index, or query the index. You'll find more information on SolrJ in [Client APIs](#).

Here's an example of using Solr Cell and SolrJ to add documents to a Solr index.

First, let's use SolrJ to create a new `SolrServer`, then we'll construct a request containing a `ContentStream` (essentially a wrapper around a file) and sent it to Solr:

```
public class SolrCellRequestDemo \{
    public static void main (String\[\] args){color} throws IOException,
    SolrServerException \{
        SolrServer server = new CommonsHttpSolrServer("http://localhost:8983/solr");
        ContentStreamUpdateRequest req = new ContentStreamUpdateRequest("/update/extract");
        req.addFile(new File("apache-solr/site/features.pdf"));
        req.setParam(ExtractingParams.EXTRACT_ONLY, "true");
        NamedList<Object> result = server.request(req);
        System.out.println("Result: " + result);
    }
}
```

This operation streams the file `features.pdf` into the Solr index.

The sample code above calls the `extract` command, but you can easily substitute other commands that are supported by Solr Cell. The key class to use is the `ContentStreamUpdateRequest`, which makes sure the `ContentStreams` are set properly. SolrJ takes care of the rest.

Note that the `ContentStreamUpdateRequest` is not just specific to Solr Cell. You can send CSV to the CSV Update handler and to any other Request Handler that works with Content Streams for updates.

Uploading Data with Index Handlers

Index Handlers are Update Handlers designed to add, delete and update documents to the index. Solr includes several of these to allow indexing documents in XML, CSV and JSON.

The example URLs given here reflect the handler configuration in the supplied `solrconfig.xml`. If the name associated with the handler is changed then the URLs will need to be modified. It is quite possible to access the same handler using more than one name, which can be useful if you wish to specify different sets of default options.

Index Handlers covered in this section:

- [XMLUpdateRequestHandler for XML-formatted Data](#)
- [XSLTRequestHandler to Transform XML Content](#)
- [CSVRequestHandler for CSV Content](#)
- [Using the JSONRequestHandler for JSON Content](#)
- [Indexing Using SolrJ](#)

XMLUpdateRequestHandler for XML-formatted Data

Configuration

The default configuration file has the update request handler configured by default.

```
<requestHandler name="/update" class="solr.XmlUpdateRequestHandler" />
```

Adding Documents

Documents are added to the index by sending an XML message to the update handler.

The XML schema recognized by the update handler is very straightforward:

- The `<add>` element introduces one more more documents to be added.
- The `<doc>` element introduces the fields making up a document.
- The `<field>` element presents the content for a specific field.

For example:

```

<add>
  <doc>
    <field name="authors">Patrick Eagar</field>
    <field name="subject">Sports</field>
    <field name="dd">796.35</field>
    <field name="numpages">128</field>
    <field name="desc"></field>
    <field name="price">12.40</field>
    <field name="title" boost="2.0">Summer of the all-rounder: Test and championship
cricket in England 1982</field>
    <field name="isbn">0002166313</field>
    <field name="yearpub">1982</field>
    <field name="publisher">Collins</field>
  </doc>
  <doc boost="2.5">
    ...
  </doc>
</add>

```

If the document schema defines a unique key, then an `/update` operation silently replaces a document in the index with the same unique key, unless the `<add>` element sets the `allowDups` attribute to `true`. If no unique key has been defined, indexing performance is somewhat faster, as no search has to be made for an existing document.

Each element has certain optional attributes which may be specified.

Command	Command Description	Optional Parameter	Parameter Description
<code><add></code>	Introduces one or more documents to be added to the index.	<code>commitWithin=number</code>	Add the document within the specified number of milliseconds
<code><doc></code>	Introduces the definition of a specific document.	<code>boost=float</code>	Default is 1.0. Sets a boost value for the document. To learn more about boosting, see Searching .
<code><field></code>	Defines a field within a document.	<code>boost=float</code>	Default is 1.0. Sets a boost value for the field.

Other optional parameters for `<add>`, including `allowDups`, `overwritePending`, and `overwriteCommitted`, are now deprecated.

Commit and Optimize Operations

The `<commit>` operation writes all documents loaded since the last commit to one or more segment files on the disk. Before a commit has been issued, newly indexed content is not visible to searches. The commit operation opens a new searcher, and triggers any event listeners that have been configured.

Commits may be issued explicitly with a `<commit/>` message, and can also be triggered from `<autocommit>` parameters in `solrconfig.xml`.

The `<optimize>` operation requests Solr to merge internal data structures in order to improve search performance. For a large index, optimization will take some time to complete, but by merging many small segment files into a larger one, search performance will improve. If you are using Solr's replication mechanism to distribute searches across many systems, be aware that after an optimize, a complete index will need to be transferred. In contrast, post-commit transfers are usually much smaller.

The `<commit>` and `<optimize>` elements accept these optional attributes:

Optional Attribute	Description
maxSegments	Default is 1. Optimizes the index to include no more than this number of segments.
waitFlush	Default is true. Blocks until index changes are flushed to disk.
waitSearcher	Default is true. Blocks until a new searcher is opened and registered as the main query searcher, making the changes visible.
expungeDeletes	Default is false. Merges segments and removes deleted documents.

Here are examples of `<commit>` and `<optimize>` using optional attributes:

```
<commit waitFlush="false" waitSearcher="false"/>
<commit waitFlush="false" waitSearcher="false" expungeDeletes="true"/>
<optimize waitFlush="false" waitSearcher="false"/>
```

Delete Operations

Documents can be deleted from the index in two ways. "Delete by ID" deletes the document with the specified ID, and can be used only if a UniqueID field has been defined in the schema. "Delete by Query" deletes all documents matching a specified query. A single delete message can contain multiple delete operations.

```
<delete>
  <id>0002166313</id>
  <id>0031745983</id>
  <query>subject:sport</query>
  <query>publisher:penguin</query>
</delete>
```

Rollback Operations

The rollback command rolls back all add and deletes made to the index since the last commit. It neither calls any event listeners nor creates a new searcher. Its syntax is simple: `<rollback/>`.

Using curl to Perform Updates with the Update Request Handler.

You can use the `curl` utility to perform any of the above commands, using its `--data-binary` option to append the XML message to the `curl` command, and generating a HTTP POST request. For example:

```
curl http://localhost:8983/update -H "Content-Type: text/xml" --data-binary '
<add>
  <doc>
    <field name="authors">Patrick Eagar</field>
    <field name="subject">Sports</field>
    <field name="dd">796.35</field>
    <field name="isbn">0002166313</field>
    <field name="yearpub">1982</field>
    <field name="publisher">Collins</field>
  </doc>
</add>'
```

For posting XML messages contained in a file, you can use the alternative form:

```
curl http://localhost:8983/update -H "Content-Type: text/xml"
--data-binary @myfile.xml
```

Short requests can also be sent using a HTTP GET command, URL-encoding the request, as in the following. Note the escaping of "<" and ">":

```
curl http://localhost:8983/update?stream.body=%3Ccommit/%3E
```

Responses from Solr take the form shown here:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <lst name="responseHeader">
    <int name="status">0</int>
    <int name="QTime">127</int>
  </lst>
</response>
```

The status field will be non-zero in case of failure. The servlet container will generate an appropriate HTML-formatted message in the case of an error at the HTTP layer.

A Simple Cross-Platform Posting Tool

For demo purposes, the file `example/exampledocs/post.jar` includes a cross-platform Java tool for POST-ing XML documents. Open a window and run:

```
java -jar post.jar <list of files with messages>
```

By default, this will contact the server at `localhost:8983`. The `"-help"` option outputs the following information on its usage:

```
SimplePostTool: version 1.2
```

This is a simple command line tool for POSTing raw XML to a Solr port. XML data can be read from files specified as command line args; as raw commandline arg strings; or via STDIN.

Examples:

```
java -Ddata=files -jar post.jar *.xml
java -Ddata=args -jar post.jar '<delete><id>42</id></delete>'
java -Ddata=stdin -jar post.jar < hd.xml
```

Other options controlled by System Properties include the Solr URL to POST to, and whether a commit should be executed. These are the defaults for all System Properties.

```
-Ddata=files
-Durl=[http://localhost:8983/solr/update|http://localhost:8983/solr/update]
-Dcommit=yes
```

For more information about the XML Update Request Handler, see <https://wiki.apache.org/solr/UpdateXmlMessages>.

XSLTRequestHandler to Transform XML Content

Configuration

The default configuration file has the update request handler configured by default, although the "lazy load" flag is set.

The XSLTRequestHandler allows you to index any XML data with the [XML <tr> command](#). You must have an XSLT stylesheet in the solr/conf/xslt directory that can transform the incoming data to the expected <add><doc/></add> format.

```
<requestHandler name="/update/xslt" startup="lazy"
class="solr.XsltUpdateRequestHandler"/>
```

Here is an example XSLT stylesheet:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
  <xsl:template match="/">
    <add>
      <xsl:apply-templates select="/random/document"/>
    </add>
  </xsl:template>

  <xsl:template match="document">
    <doc boost="5.5">
      <xsl:apply-templates select="*" />
    </doc>
  </xsl:template>

  <xsl:template match="node">
    <field name="{@name}">
      <xsl:if test="@enhance!=''">
        <xsl:attribute name="boost"><xsl:value-of select="@enhance"/></xsl:attribute>
      </xsl:if>
      <xsl:value-of select="@value"/>
    </field>
  </xsl:template>
</xsl:stylesheet>
```

CSVRequestHandler for CSV Content

Configuration

The default configuration file has the update request handler configured by default, although the "lazy load" flag is set.

```
<requestHandler name="/update/csv" class="solr.CSVRequestHandler" startup="lazy" />
```

Parameters

The CSV handler allows the specification of many parameters in the URL in the form: `f.parameter.optional_fieldname=value`.

The table below describes the parameters for the update handler.

Parameter	Usage	Global (g) or Per Field (f)	Example
separator	Character used as field separator; default is ","	g,(f: see split)	separator=%
trim	If true, remove leading and trailing whitespace from values. Default=false.	g,f	f.isbn.trim=true trim=false
header	Set to true if first line of input contains field names. These will be used if the fieldnames parameter is absent.	g	
fieldnames	Comma separated list of field names to use when adding documents.	g	fieldnames=isbn,price,title
skip	Comma separated list of field names to skip.	g	skip=uninteresting,shoesize
skipLines	Number of lines to discard in the input stream before the CSV data starts, including the header, if present. Default=0.	g	skipLines=5
encapsulator	The character optionally used to surround values to preserve characters such as the CSV separator or whitespace. This standard CSV format handles the encapsulator itself appearing in an encapsulated value by doubling the encapsulator.	g,(f: see split)	encapsulator="

escape	The character used for escaping CSV separators or other reserved characters. If an escape is specified, the encapsulator is not used unless also explicitly specified since most formats use either encapsulation or escaping, not both	g	escape=\
keepEmpty	Keep and index zero length (empty) fields. Default=false.	g,f	f.price.keepEmpty=true
map	Map one value to another. Format is value:replacement (which can be empty.)	g,f	map=left:right f.subject.map=history:bunk
split	If true, split a field into multiple values by a separate parser.	f	
overwrite	If true (the default), check for and overwrite duplicate documents, based on the uniqueKey field declared in the Solr schema. If you know the documents you are indexing do not contain any duplicates then you may see a considerable speed up setting this to false.	g	
commit	Issues a commit after the data has been ingested.	g	
commitWithin	Add the document within the specified number of milliseconds.	g	commitWithin=10000

For more information on the CSV Update Request Handler, see <https://wiki.apache.org/solr/UpdateCSV>.

Using the JSONRequestHandler for JSON Content

JSON formatted update requests may be sent to Solr using the `/solr/update/json` URL. All of the normal methods for uploading content are supported.

Configuration

The default configuration file has the update request handler configured by default, although the "lazy load" flag is set.

```
<requestHandler name="/update/json" class="solr.JsonUpdateRequestHandler"
startup="lazy" />
```

Examples

There is a sample JSON file at `example/exampldocs/books.json` that you can use to add documents to the Solr example server.

```
cd example/exampldocs
curl 'http://localhost:8983/solr/update/json?commit=true'
--data-binary @books.json -H 'Content-type:application/json'
```

Adding `commit=true` to the URL makes the documents immediately searchable.

You should now be able to query for the newly added documents:

`http://localhost:8983/solr/select?q=title:monsters&wt=json&indent=true` returns:

```
{
  "responseHeader":{
    "status":0,
    "QTime":2,
    "params":{
      "indent":"true",
      "wt":"json",
      "q":"title:monsters"}},
  "response":{"numFound":1,"start":0,"docs":[
    {
      "id":"978-1423103349",
      "author":"Rick Riordan",
      "series_t":"Percy Jackson and the Olympians",
      "sequence_i":2,
      "genre_s":"fantasy",
      "inStock":true,
      "price":6.49,
      "pages_i":304,
      "title":[
        "The Sea of Monsters"],
      "cat":["book","paperback"]}]
  }
}
```

Update Commands

The JSON update handler accepts all of the update commands that the XML update handler supports, through a straightforward mapping. Multiple commands may be contained in one message:

```
{
  "add": {
    "doc": {
      "id": "DOC1",
      "my_boosted_field": {          /* use a map with boost/value for a boosted field */
        "boost": 2.3,
        "value": "test"
      },
      "my_multivalued_field": [ "aaa", "bbb" ] /* use an array for a multi-valued field
    */
    }
  },
  "add": {
    "commitWithin": 5000,          /* commit this document within 5 seconds */
    "overwrite": false,           /* don't check for existing documents with the same
uniqueKey */
    "boost": 3.45,                /* a document boost */
    "doc": {
      "f1": "v1",
      "f1": "v2"
    }
  },
  "commit": {},
  "optimize": { "waitFlush":false, "waitSearcher":false },

  "delete": { "id":"ID" },       /* delete by ID */
  "delete": { "query":"QUERY" } /* delete by query */
}
```

 Comments are not allowed JSON, but duplicate names are.

As with other update handlers, parameters such as `commit`, `commitWithin`, `optimize`, and `overwrite` may be specified in the URL instead of in the body of the message.

For more information about the JSON Update Request Handler, see <https://wiki.apache.org/solr/UpdateJSON>.

Indexing Using SolrJ

Use of the the SolrJ client library is covered in [Client APIs](#).

Uploading Structured Data Store Data with the Data Import Handler

Many search applications store the content to be indexed in a structured data store, such as a relational database. The Data Import Handler (DIH) provides a mechanism for importing content from a data store and indexing it. In addition to relational databases, DIH can index content from HTTP based data sources such as RSS and ATOM feeds, e-mail repositories, and structured XML where an XPath processor is used to generate fields.

 The DataImportHandler jars are no longer included in the Solr WAR. You should add them to Solr's lib directory, or reference them via the `<lib>` directive in `solrconfig.xml`.

For more information about the Data Import Handler, see <https://wiki.apache.org/solr/DataImportHandler>.

Topics covered in this section:

- [Concepts and Terminology](#)
- [Configuration](#)
- [Data Import Handler Commands](#)
- [Data Sources](#)
- [Entity Processors](#)
- [Transformers](#)
- [Special Commands for the Data Import Handler](#)
- [The Data Import Handler Development Console](#)

Concepts and Terminology

Descriptions of the Data Import Handler use several familiar terms, such as entity and processor, in specific ways, as explained in the table below.

Term	Definition
Datasource	As its name suggests, a datasource defines the location of the data of interest. For a database, it's a DSN. For an HTTP datasource, it's the base URL.

Entity	Conceptually, an entity is processed to generate a set of documents, containing multiple fields, which (after optionally being transformed in various ways) are sent to Solr for indexing. For a RDBMS data source, an entity is a view or table, which would be processed by one or more SQL statements to generate a set of rows (documents) with one or more columns (fields).
Processor	An entity processor does the work of extracting content from a data source, transforming it, and adding it to the index. Custom entity processors can be written to extend or replace the ones supplied.
Transformer	Each set of fields fetched by the entity may optionally be transformed. This process can modify the fields, create new fields, or generate multiple rows/documents from a single row. There are several built-in transformers in the DIH, which perform functions such as modifying dates and stripping HTML. It is possible to write custom transformers using the publicly available interface.

Configuration

The Data Import Handler has to be registered in `solrconfig.xml`. For example:

```
<requestHandler name="/dataimport"
class="org.apache.solr.handler.dataimport.DataImportHandler">
  <lst name="defaults">
    <str name="config">/path/to/my/DIHconfigfile.xml</str>
  </lst>
</requestHandler>
```

You can have multiple DIH configuration files. Each file would require a separate definition in the `solrconfig.xml` file, specifying a path to the file.

The DIH configuration file contains specifications for the data source, how to fetch data, what data to fetch, and how to process it to generate the Solr documents to be posted to the index.

There is a sample DIH application distributed with Solr in the directory `example/example-DIH`. This accesses a small `hsqldb` database. Details of how to run this example can be found in the `README.txt` file. Its DIH configuration can be found in the file `example/example-DIH/solr/db/conf/db-data-config.xml`.

An annotated configuration file, based on the sample, is shown below. It extracts fields from the four tables defining a simple product database, with this schema.

```

<dataConfig>

<!-- The first element is the dataSource, in this case an HSQLDB database.
      The path to the JDBC driver and the JDBC URL and login credentials are all
      specified here.
      Other permissible attributes include whether or not to autocommit to Solr, the
      batchsize
      used in the JDBC connection, a 'readOnly' flag -->

<dataSource
  driver="org.hsqldb.jdbcDriver"
  url="jdbc:hsqldb:./example-DIH/hsqldb/ex"
  user="sa"
  password="mypass" />

<!-- a 'document' element follows, containing multiple 'entity' elements.
      Note that 'entity' elements can be nested, and this allows the entity
      relationships in the sample database to be mirrored here, so that we can
      generate a denormalized Solr record which may include multiple features
      for one item, for instance -->

<!--The possible attributes for the entity element are described below.
      Entity elements may contain one or more 'field' elements, which map
      the data source field names to Solr fields, and optionally specify
      per-field transformations -->
  
```

```

    <document name="products">

<!-- this entity is the 'root' entity. -->

    <entity name="item" pk="ID"
        query="select * from item"
        deltaQuery="select id from item where last_modified >
'$\{dataimporter.last_index_time\}'">
        <field column="ID" name="id" />

<!-- multiple Solr fields are generated from a single column in the table -->

        <field column="NAME" name="name" />
        <field column="NAME" name="nameSort" />
        <field column="NAME" name="alphaNameSort" />

<!-- This entity is nested and reflects the one-to-many relationship between an item
and its multiple features.
    Note the use of variables; $\{item.ID\} is the value of the column 'ID' for the
current item
    ('item' referring to the entity name) -->

        <entity name="feature" pk="ITEM_ID"
            query="select DESCRIPTION from FEATURE where ITEM_ID='$\{item.ID\}'"
            deltaQuery="select ITEM_ID from FEATURE where last_modified >
'$\{dataimporter.last_index_time\}'"
            parentDeltaQuery="select ID from item where ID=$\{feature.ITEM_ID\}">
            <field name="features" column="DESCRIPTION" />
        </entity>

        <entity name="item_category" pk="ITEM_ID, CATEGORY_ID"
            query="select CATEGORY_ID from item_category where ITEM_ID='$\{item.ID\}'"
            deltaQuery="select ITEM_ID,CATEGORY_ID from item_category where last_modified
> '$\{dataimporter.last_index_time\}'"
            parentDeltaQuery="select ID from item where ID=$\{item_category.ITEM_ID\}">
            <entity name="category" pk="ID"
                query="select DESCRIPTION from category where ID =
'$\{item_category.CATEGORY_ID\}'"
                deltaQuery="select ID from category where last_modified >
'$\{dataimporter.last_index_time\}'"
                parentDeltaQuery="select ITEM_ID, CATEGORY_ID from item_category where
CATEGORY_ID=$\{category.ID\}">
                <field column="description" name="cat" />
            </entity>
        </entity>
    </entity>
</document>

```

Data Import Handler Commands

DIH commands are sent to Solr via an HTTP request. The following operations are supported.

Command	Description
abort	Aborts an ongoing operation. The URL is <code>http://<host>:<port>/solr/dataimport?command=abort</code> .
delta-import	For incremental imports and change detection. The command is of the form <code>http://<host>:<port>/solr/dataimport?command=delta-import</code> . It supports the same <code>clean</code> , <code>commit</code> , <code>optimize</code> and <code>debug</code> parameters as <code>full-import</code> command.
full-import	A Full Import operation can be started with a URL of the form <code>http://<host>:<port>/solr/dataimport?command=full-import</code> . The command returns immediately. The operation will be started in a new thread and the <code>status</code> attribute in the response should be shown as <i>busy</i> . The operation may take some time depending on the size of dataset. Queries to Solr are not blocked during full-imports. When a full-import command is executed, it stores the start time of the operation in a file located at <code>conf/dataimport.properties</code> . This stored timestamp is used when a delta-import operation is executed. For a list of parameters that can be passed to this command, see below.
reload-config	If the configuration file has been changed and you wish to reload it without restarting Solr, run the command <code>http://<host>:<port>/solr/dataimport?command=reload-config</code> .
status	The URL is <code>http://<host>:<port>/solr/dataimport?command=status</code> . It returns statistics on the number of documents created, deleted, queries run, rows fetched, status, and so on.

Parameters for the full-import Command

The `full-import` command accepts the following parameters:

Parameter	Description
clean	Default is true. Tells whether to clean up the index before the indexing is started.
commit	Default is true. Tells whether to commit after the operation.

debug	Default is false. Runs the command in debug mode. It is used by the interactive development mode. Note that in debug mode, documents are never committed automatically. If you want to run debug mode and commit the results too, add <code>commit=true</code> as a request parameter.
entity	The name of an entity directly under the <code><document></code> tag in the configuration file. Use this to execute one or more entities selectively. Multiple "entity" parameters can be passed on to run multiple entities at once. If nothing is passed, all entities are executed.
optimize	Default is true. Tells Solr whether to optimize after the operation.

Data Sources

A data source specifies the origin of data and its type. Somewhat confusingly, some data sources are configured within the associated entity processor. Data sources can also be specified in `solrconfig.xml`, which is useful when you have multiple environments (for example, development, QA, and production) differing only in their data sources.

You can create a custom data source by writing a class that extends `org.apache.solr.handler.dataimport.DataSource`.

The mandatory attributes for a data source definition are its name and type. The name identifies the data source to an Entity element.

The types of data sources available are described below.

ContentStreamDataSource

This takes the POST data as the data source. This can be used with any EntityProcessor that uses a `DataSource<Reader>`.

FieldReaderDataSource

This can be used where a database field contains XML which you wish to process using the `XpathEntityProcessor`. You would set up a configuration with both JDBC and FieldReader data sources, and two entities, as follows:

```

<dataSource name = "a1" driver="org.hsqldb.jdbcDriver" ... />
  <dataSource name="a2" type=FieldReaderDataSource" />

  <!-- processor for database -->

  <entity name ="e1" dataSource="a1" processor="SQLEntityProcessor" pk="docid"
    query="select * from t1 ...">

<!-- nested XpathEntity; the field in the parent which is to be used for
  Xpath is set in the 'datafield attribute inplace of the "url" attribute -->

<entity name="e2"
  dataSource="a2"
  processor="XPathEntityProcessor"
  dataField="e1.fieldToUseForXPath"

<!-- Xpath configuration follows -->

  ...
  </entity>
</entity>

```

FileDataSource

This can be used like an [URLDataSource](#), but is used to fetch content from files on disk. The only difference from [URLDataSource](#), when accessing disk files, is how a pathname is specified. The signature is as follows:

```
public class FileDataSource extends DataSource<Reader>
```

This data source accepts these optional attributes.

Optional Attribute	Description
basePath	The base path relative to which the value is evaluated if it is not absolute.
encoding	If the files are to be read in an encoding that is not same as the platform encoding.

HTTPDataSource

 As of Solr 1.4, HTTPDataSource is deprecated in favor of URLDataSource, which is described below.

This data source can be used to fetch content from a URL (`http://` or `file://`). It's typically used with the XpathEntityProcessor. As the example below shows, this data source accepts the same attributes as the URLDataSource.

```
<!-- baseUrl, encoding, connectionTimeout(ms) and readTimeout(ms) are all optional -->
<dataSource name="x"
  type="HTTPDataSource"
  baseUrl="http://host:port/"
  encoding="UTF-8"
  connectionTimeout="5000"
  readTimeout="10000"/>
```

JdbcDataSource

This is the default datasource. It's used with the [SQLEntityProcessor](#). See the example in the [FieldReaderDataSource](#) section for details on configuration.

URLDataSource

 As of Solr 1.4, we recommend that you use this data source rather than HTTPDataSource.

This data source is often used with XPathEntityProcessor to fetch content from an underlying `file://` or `http://` location. The signature is as follows:

```
public class URLDataSource extends DataSource<Reader>
```

Here's an example:

```
<dataSource name="a"
  type="URLDataSource"
  baseUrl="http://host:port/"
  encoding="UTF-8"
  connectionTimeout="5000"
  readTimeout="10000"/>
```

The `URLDataSource` type accepts these optional parameters:

Optional Parameter	Description
<code>baseUrl</code>	Specifies a new <code>baseUrl</code> for pathnames. You can use this to specify host/port changes between Dev/QA/Prod environments. Using this attribute isolates the changes to be made to the <code>solrconfig.xml</code>
<code>connectionTimeout</code>	Specifies the length of time in milliseconds after which the connection should time out. The default value is 5000ms.
<code>encoding</code>	By default the encoding in the response header is used. You can use this property to override the default encoding.
<code>readTimeout</code>	Specifies the length of time in milliseconds after which a read operation should time out. The default value is 10000ms.

Entity Processors

Entity processors extract data, transform it, and add it to a Solr index. Examples of entities include views or tables in a data store.

Each processor has its own set of attributes, described in its own section below. In addition, there are non-specific attributes common to all entities which may be specified.

Attribute	Use
<code>datasource</code>	The name of a <code>dataSource</code> . Used if there are multiple <code>datasources</code> , specified, in which case each one must have a name.
<code>name</code>	Required. The unique name used to identify an entity.
<code>pk</code>	The primary key for the entity. It is optional, and required only when using <code>delta-imports</code> . It has no relation to the <code>uniqueKey</code> defined in <code>schema.xml</code> but they can both be the same. It is mandatory if you do <code>delta-imports</code> and then refers to the column name in <code>\${dataimporter.delta.<column-name>}</code> which is used as the primary key.
<code>processor</code>	Default is <code>SQLEntityProcessor</code> . Required only if the <code>datasource</code> is not RDBMS.
<code>onError</code>	Permissible values are (abort skip continue) . The default value is 'abort'. 'Skip' skips the current document. 'Continue' ignores the error and processing continues.

preImportDeleteQuery	Before a full-import command, use this query this to cleanup the index instead of using '*:*'. This is honored only on an entity that is an immediate sub-child of <document>.
postImportDeleteQuery	Similar to the above, but executed after the import has completed.
rootEntity	By default the entities immediately under the <document> are root entities. If this attribute is set to false, the entity directly falling under that entity will be treated as the root entity (and so on). For every row returned by the root entity, a document is created in Solr.
transformer	Optional. One or more transformers to be applied on this entity.

The SQL Entity Processor

The SqlEntityProcessor is the default processor. The associated [data source](#) should be a JDBC URL.

The entity attributes specific to this processor are shown in the table below.

Attribute	Use
query	Required. The SQL query used to select rows.
deltaQuery	SQL query used if the operation is delta-import. This query selects the primary keys of the rows which will be parts of the delta-update. The pks will be available to the deltaImportQuery through the variable <code>\${dataimporter.delta.<column-name>}</code> .
parentDeltaQuery	SQL query used if the operation is delta-import.
deletedPkQuery	SQL query used if the operation is delta-import.
deltaImportQuery	SQL query used if the operation is delta-import. If this is not present, DIH tries to construct the import query by(after identifying the delta) modifying the 'query' (this is error prone). There is a namespace <code>\${dataimporter.delta.<column-name>}</code> which can be used in this query. For example, <code>select * from tbl where id=\${dataimporter.delta.id}</code> .

The XPathEntityProcessor

This processor is used when indexing XML formatted data. The data source is typically [URLDataSource](#) or [FileDataSource](#). Xpath can also be used with the [FileListEntityProcessor](#) described below, to generate a document from each file.

The entity attributes unique to this processor are shown below.

Attribute	Use
Processor	Required. Must be set to "XPathEntityProcessor".
url	Required. HTTP URL or file location.
stream	Optional: Set to true for a large file or download.
forEach	Required unless you define <code>useSolrAddSchema</code> . The XPath expression which demarcates each record. This will be used to set up the processing loop.
xsl	Optional: Its value (a URL or filesystem path) is the name of a resource used as a preprocessor for applying the XSL transformation.
useSolrAddSchema	Set this to true if the content is in the form of the standard Solr update XML schema.
flatten	Optional: If set true, then text from under all the tags is extracted into one field.

Each field element in the entity can have the following attributes as well as the default ones.

Attribute	Use
xpath	Required. The XPath expression which will extract the content from the record for this field. Only a subset of XPath syntax is supported.
commonField	Optional. If true, then when this field is encountered in a record it will be copied to future records when creating a Solr document.

Example:

```
<!-- slashdot RSS Feed --->
<dataConfig>
  <dataSource type="HttpDataSource" />
  <document>
<entity name="slashdot"
  pk="link"
  url="http://rss.slashdot.org/Slashdot/slashdot"
  processor="XPathEntityProcessor"

  <!-- forEach sets up a processing loop ; here there are two expressions-->

forEach="/RDF/channel | /RDF/item"
transformer="DateFormatTransformer">
  <field column="source"
    xpath="/RDF/channel/title"
    commonField="true" />
  <field column="source-link"
    xpath="/RDF/channel/link"
    commonField="true"/>
  <field column="subject"
    xpath="/RDF/channel/subject"
    commonField="true" />
  <field column="title"
    xpath="/RDF/item/title" />
  <field column="link"
    xpath="/RDF/item/link" />
  <field column="description"
    xpath="/RDF/item/description" />
  <field column="creator"
    xpath="/RDF/item/creator" />
  <field column="item-subject"
    xpath="/RDF/item/subject" />
  <field column="date"
    xpath="/RDF/item/date"
    dateTimeFormat="yyyy-MM-dd'T'hh:mm:ss" />
  <field column="slash-department"
    xpath="/RDF/item/department" />
  <field column="slash-section"
    xpath="/RDF/item/section" />
  <field column="slash-comments"
    xpath="/RDF/item/comments" />
  </entity>
  </document>
</dataConfig>
```

<http://wiki.apache.org/solr/MailEntityProcessor>

The FileListEntityProcessor

This processor is basically a wrapper, and is designed to generate a set of files satisfying conditions specified in the attributes which can then be passed to another processor, such as the [XPathEntityProcessor](#). The entity information for this processor would be nested within the FileListEntity entry. It generates four implicit fields: `fileAbsolutePath`, `fileSize`, `fileLastModified`, `fileName` which can be used in the nested processor. This processor does not use a data source.

The attributes specific to this processor are described in the table below:

Attribute	Use
<code>fileName</code>	Required. A regular expression pattern to identify files to be included.
<code>basedir</code>	Required. The base directory (absolute path).
<code>recursive</code>	Whether to search directories recursively. Default is 'false'.
<code>excludes</code>	A regular expression pattern to identify files which will be excluded.
<code>newerThan</code>	A date in the format <code>yyyy-MM-ddHH:mm:ss</code> or a date math expression (<code>NOW - 2YEARS</code>).
<code>olderThan</code>	A date, using the same formats as <code>newerThan</code> .
<code>rootEntity</code>	This should be set to false. This ensures that each row (filepath) emitted by this processor is considered to be a document.
<code>dataSource</code>	Must be set to null.

The example below shows the combination of the FileListEntityProcessor with another processor which will generate a set of fields from each file found.

```

<dataConfig>
<dataSource type="FileDataSource"/><document>
  <!-- this outer processor generates a list of files satisfying the conditions
    specified in the attributes -->
  <entity name="f" processor="FileListEntityProcessor"
    fileName="*.xml"
    newerThan="'NOW-30DAYS'"
    recursive="true"
    rootEntity="false"
    dataSource="null"
    baseDir="/my/document/directory">

    <!-- this processor extracts content using Xpath from each file found -->

  <entity name="nested" processor="XPathEntityProcessor"
    forEach="/rootelement" url="{f.fileAbsolutePath}" >
    <field column="name" xpath="/rootelement/name"/>
    <field column="number" xpath="/rootelement/number"/>
  </entity>
</entity>
</document>
</dataConfig>

```

LineEntityProcessor

This EntityProcessor reads all content from the data source on a line by line basis and returns a field called `rawLine` for each line read. The content is not parsed in any way; however, you may add transformers to manipulate the data within the `rawLine` field, or to create other additional fields.

The lines read can be filtered by two regular expressions specified with the `acceptLineRegex` and `omitLineRegex` attributes. The table below describes the LineEntityProcessor's attributes:

Attribute	Description
<code>url</code>	A required attribute that specifies the location of the input file in a way that is compatible with the configured data source. If this value is relative and you are using <code>FileDataSource</code> or <code>URLDataSource</code> , it assumed to be relative to <code>baseLoc</code> .
<code>acceptLineRegex</code>	An optional attribute that if present discards any line which does not match the <code>regExp</code> .
<code>omitLineRegex</code>	An optional attribute that is applied after any <code>acceptLineRegex</code> and that discards any line which matches this <code>regExp</code> .

For example:

```
<entity name="jc"
  processor="LineEntityProcessor"
  acceptLineRegex="^.*\.xml$"
  omitLineRegex="/obsolete"
  url="file:///Volumes/ts/files.lis"
  rootEntity="false"
  dataSource="myURIREader1"
  transformer="RegexTransformer,DateFormatTransformer"
  >
  ...
```

While there are use cases where you might need to create a Solr document for each line read from a file, it is expected that in most cases that the lines read by this processor will consist of a pathname, which in turn will be consumed by another EntityProcessor, such as [XPathEntityProcessor](#).

PlainTextEntityProcessor

This EntityProcessor reads all content from the data source into an single implicit field called `plainText`. The content is not parsed in any way, however you may add transformers to manipulate the data within the `plainText` as needed, or to create other additional fields.

For example:

```
<entity processor="PlainTextEntityProcessor" name="x" url="http://abc.com/a.txt"
  dataSource="data-source-name">
  <!-- copies the text to a field called 'text' in Solr-->
  <field column="plainText" name="text"/>
</entity>
```

Ensure that the `dataSource` is of type `DataSource<Reader>` (`FileDataSource`, `URLDataSource`).

Transformers

Transformers manipulate the fields in a document returned by an entity. A transformer can create new fields or modify existing ones. You must tell the entity which transformers your import operation will be using, by adding an attribute containing a comma separated list to the `<entity>` element.

```
<entity name="abcde"
  transformer="org.apache.solr...,my.own.transformer,..." />
```

Specific transformation rules are then added to the attributes of a `<field>` element, as shown in the examples below. The transformers are applied in the order in which they are specified in the transformer attribute.

The Data Import Handler contains several built-in transformers. You can also write your own custom transformers, as described in the Solr Wiki (see <http://wiki.apache.org/solr/DIHCustomTransformer>). The ScriptTransformer (described below) offers an alternative method for writing your own transformers.

Solr 3.4 includes the following built-in transformers:

Transformer Name	Use
ClobTransformer	Used to create a String out of a Clob type in database.
DateFormatTransformer	Parse date/time instances.
HTMLStripTransformer	Strip HTML from a field.
LogTransformer	Used to log data to log files or a console.
NumberFormatTransformer	Uses the NumberFormat class in java to parse a string into a number.
RegexTransformer	Use regular expressions to manipulate fields.
ScriptTransformer	Write transformers in Javascript or any other scripting language supported by Java. Requires Java 6.
TemplateTransformer	Transform a field using a template.

These transformers are described below.

ClobTransformer

You can use the ClobTransformer to create a string out of a CLOB in a database. A CLOB is a character large object: a collection of character data typically stored in a separate location that is referenced in the database. See http://en.wikipedia.org/wiki/Character_large_object. Here's an example of invoking the ClobTransformer.

```
<entity name="e" transformer="ClobTransformer" ..>
  <field column="hugeTextField" clob="true" />
  ...
</entity>
```

The ClobTransformer accepts these attributes:

Attribute	Description
clob	Boolean value to signal if ClobTransformer should process this field or not. If this attribute is omitted, then the corresponding field is not transformed.
sourceColName	The source column to be used as input. If this is absent source and target are same

The DateFormatTransformer

This transformer converts dates from one format to another. This would be useful, for example, in a situation where you wanted to convert a field with a fully specified date/time into a less precise date format, for use in faceting.

DateFormatTransformer applies only on the fields with an attribute `dateTimeFormat`. Other fields are not modified.

This transformer recognizes the following attributes:

Attribute	Description
dateTimeFormat	The format used for parsing this field. This must comply with the syntax of the JavaSimpleDateFormat class.
sourceColName	The column on which the dateFormat is to be applied. If this is absent source and target are same.

Here's example code which would return the date rounded up to the month "2007-JUL":

```
<entity name="en" pk="id" transformer="DateTimeTransformer" ... >
  ...
  <field column="date"
    sourceColName="fulldate"
    dateTimeFormat="yyyy-MMM" />
</entity>
```

The HTMLStripTransformer

You can use this transformer to strip HTML out of a field. For example:

```
<entity name="e" transformer="HTMLStripTransformer" ..>
<field column="htmlText" stripHTML="true" />
...
</entity>
```

There is one attribute for this transformer, `stripHTML`, which is a boolean value (true/false) to signal if the HTMLStripTransformer should process the field or not.

The LogTransformer

You can use this transformer to log data to the console or log files. For example:

```
<entity ...
transformer="LogTransformer"
logTemplate="The name is ${e.name\}" logLevel="debug" >
....
</entity>
```

Unlike other transformers, the LogTransformer does not apply to any field, so the attributes are applied on the entity itself.

The NumberFormatTransformer

Use this transformer to parse a number from a string, converting it into the specified format, and optionally using a different locale.

NumberFormatTransformer will be applied only to fields with an attribute `formatStyle`.

This transformer recognizes the following attributes:

Attribute	Description
<code>formatStyle</code>	The format used for parsing this field. The value of the attribute must be one of (<code>number</code> <code>percent</code> <code>integer</code> <code>currency</code>). This uses the semantics of the Java <code>NumberFormat</code> class.
<code>sourceColName</code>	The column on which the <code>NumberFormat</code> is to be applied. This attribute is absent. The source column and the target column are the same.
<code>locale</code>	The locale to be used for parsing the strings. If this is absent, the system's default locale is used. It must be specified as language-country. For example, <code>en-US</code> .

For example:

```

<entity name="en" pk="id" transformer="NumberFormatTransformer" ...>
  ...

<!-- treat this field as UK pounds -->

<field name="price_uk"
  column="price"
  formatStyle="currency"
  locale="en-UK" />
</entity>

```

The RegexTransformer

The regex transformer helps in extracting or manipulating values from fields (from the source) using Regular Expressions. The actual class name is `org.apache.solr.handler.dataimport.RegexTransformer`. But as it belongs to the default package the package-name can be omitted.

The table below describes the attributes recognized by the regex transformer.

Attribute	Description
regex	The regular expression that is used to match against the column or sourceColName's value(s). If <code>replaceWith</code> is absent, each <i>regex group</i> is taken as a value and a list of values is returned.
sourceColName	The column on which the regex is to be applied. If not present, then the source and target are identical.
splitBy	Used to split a string. It returns a list of values.
groupNames	A comma separated list of field column names, used where the regex contains groups and each group is to be saved to a different field. If some groups are not to be named leave a space between commas.
replaceWith	Used along with <code>regex</code> . It is equivalent to the method <code>new String(<sourceColVal>).replaceAll(<regex>, <replaceWith>)</code> .

Here is an example of configuring the regex transformer:

```
<entity name="foo" transformer="RegexTransformer"
query="select full_name , emailids from foo"/>
... />
  <field column="full_name"/>
  <field column="firstName" regex="Mr(\w*)\b.*" sourceColName="full_name"/>
  <field column="lastName" regex="Mr.*?\b(\w*)" sourceColName="full_name"/>

  <!-- another way of doing the same -->

  <field column="fullName" regex="Mr(\w*)\b(.*)" groupNames="firstName,lastName"/>
  <field column="mailId" splitBy="," sourceColName="emailids"/>
</entity>
```

In this example, `regex` and `sourceColName` are custom attributes used by the transformer. The transformer reads the field `full_name` from the resultset and transforms it to two new target fields, `firstName` and `lastName`. Even though the query returned only one column, `full_name`, in the result set, the Solr document gets two extra fields `firstName` and `lastName` which are "derived" fields. These new fields are only created if the regex matches.

The `emailids` field in the table can be a comma-separated value. It ends up producing one or more email IDs, and we expect the `mailId` to be a multivalued field in Solr.

Note that this transformer can either be used to split a string into tokens based on a `splitBy` pattern, or to perform a string substitution as per `replaceWith`, or it can assign groups within a pattern to a list of `groupNames`. It decides what it is to do based upon the above attributes `splitBy`, `replaceWith` and `groupNames` which are looked for in order. This first one found is acted upon and other unrelated attributes are ignored.

The ScriptTransformer

The script transformer allows arbitrary transformer functions to be written in any scripting language supported by Java, such as Javascript, JRuby, Jython, Groovy, or BeanShell. Javascript is integrated into Java 6; you'll need to integrate other languages yourself.

Each function you write must accept a row variable (which corresponds to a Java `Map<String, Object>`, thus permitting `get`, `put`, `remove` operations). Thus you can modify the value of an existing field or add new fields. The return value of the function is the returned object.

The script is inserted into the DIH configuration file file at the top level and is called once for each row.

Here is a simple example.

```

<dataconfig>
  <!-- simple script to generate a new row, converting a temperature from Fahrenheit
to Centigrade -->
  <script>
<CDATA
  function f2c(row) { var tempf, tempc; tempf = row.get('temp_f'); if (tempf !=
null) {   tempc = (tempf - 32.0)*5.0/9.0
    row.put('temp_c', temp_c);
  }
  return row;
  }
  >
</script>
  <document>
  <!-- the function is specified as an entity attribute -->
  <entity name="e1" pk="id" transformer="script:f2c" query="select * from X">
    ....
  </entity>
</document>
</dataConfig>

```

The TemplateTransformer

You can use the template transformer to construct or modify a field value, perhaps using the value of other fields. You can insert extra text into the template.

```

<entity name="en" pk="id" transformer="TemplateTransformer" ...>
  ...
  <!-- generate a full address from fields containing the component parts -->
  <field column="full_address"
  template="$en.\{street\},$en\{city\},$en\{zip\}" />
</entity>

```

Special Commands for the Data Import Handler

You can pass special commands to the DIH by adding any of the variables listed below to any row returned by any component:

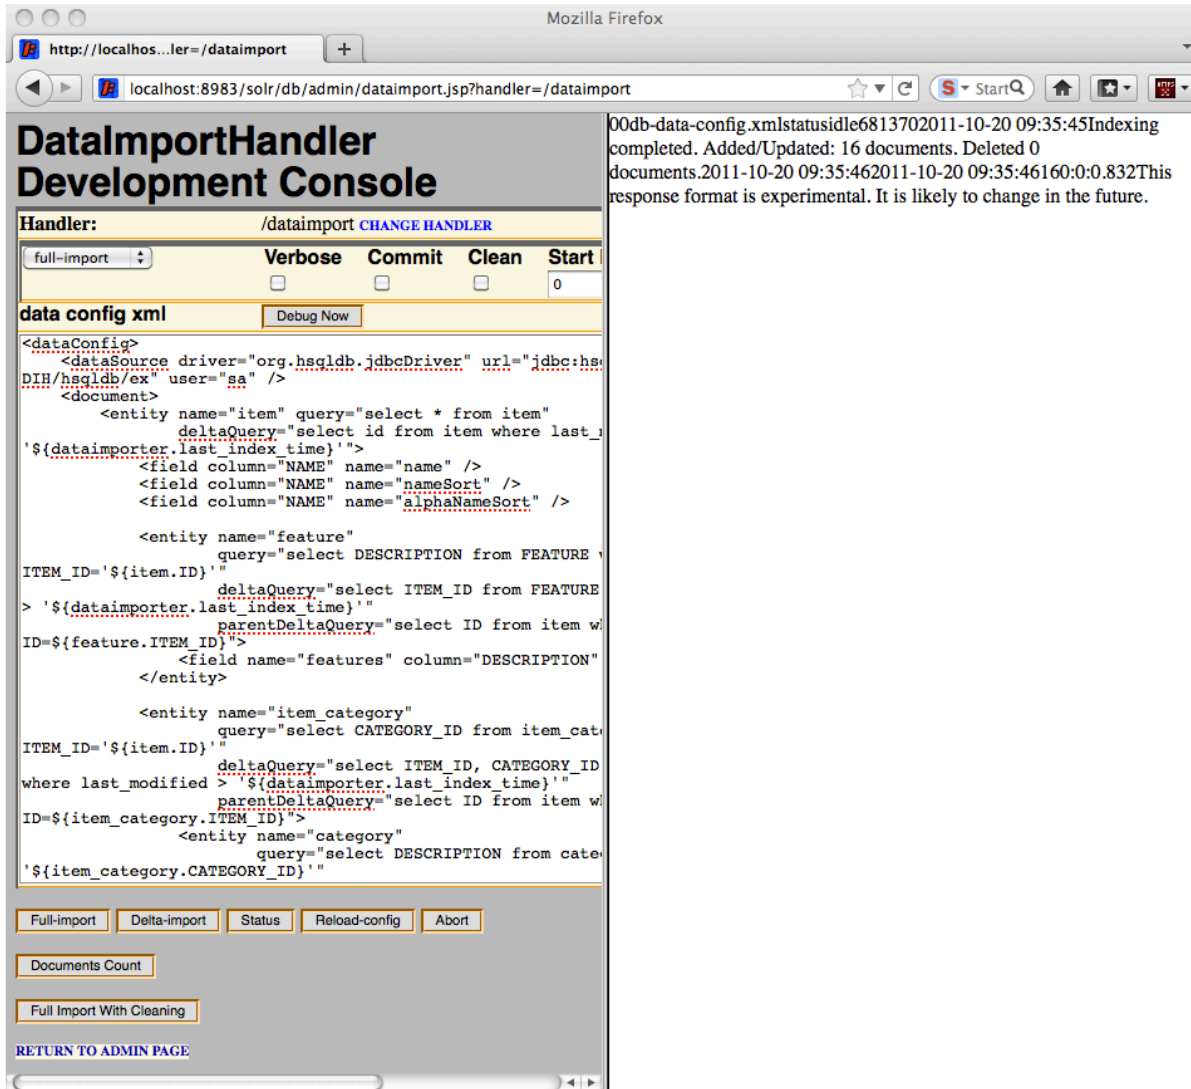

Variable	Description
\$skipDoc	Skip the current document; that is, do not add it to Solr. The value can be the string true false.

<code>\$skipRow</code>	Skip the current row. The document will be added with rows from other entities. The value can be the string <code>true false</code>
<code>\$docBoost</code>	Boost the current document. The boost value can be a number or the <code>toString</code> conversion of a number.
<code>\$deleteDocById</code>	Delete a document from Solr with this ID. The value has to be the <code>uniqueKey</code> value of the document.
<code>\$deleteDocByQuery</code>	Delete documents from Solr using this query. The value must be a Solr Query.

The Data Import Handler Development Console

The Data Import Handler includes a browser-based console to help with development. You can access the console at this address: `http://_host_:_port_/solr/admin/dataimport.jsp`.

The screenshot below shows the DIH Development Console.

The Data Import Handler Console

The console features two panels: the left-hand panel holds input (a `dataconfig.xml` file in the `conf/` directory), and the right-hand panel shows output.

When you click the **Debug Now** button, the console runs the configuration and shows the documents created.

You can configure the start and rows parameters to debug a specific range of documents: for example, documents 115 to 118 as shown in the figure below.

Handler: /dataimport [CHANGE HANDLER](#)

full-import	Verbose	Commit	Clean	Start Row	No. of Rows
<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	115	118

data config xml [Debug Now](#)

```
<dataConfig>
  <dataSource driver="org.hsqldb.jdbcDriver" url="jdbc:hsqldb:./example-
  DIH/hsqldb/ex" user="sa" />
  <document>
    <entity name="item" query="select * from item"
      deltaQuery="select id from item where last_modified >
      '${dataimporter.last_index_time}'">
      <field column="NAME" name="name" />
      <field column="NAME" name="nameSort" />
      <field column="NAME" name="alphaNameSort" />
    </entity>
    <entity name="feature"
      query="select DESCRIPTION from FEATURE where

Limiting Output to a Specific Set of Rows

Choose the "verbose" option, as shown in the figure below, to see details about the intermediate steps in a response: the original data the query emitted, the data that went into the transformer, and the data that the transformer then produced.

The screenshot shows the Solr DataImportHandler Development Console. The main area displays the handler configuration and a table of rows. The 'data config xml' section shows the following XML:

```
<dataConfig>
  <dataSource driver="org.hsqldb.jdbcDriver" url="jdbc:hsqldb://example:.
  DIH/hsqldb/ex" user="sa" />
  <document>
    <entity name="item" query="select * from item"
      deltaQuery="select id from item where last_modified >
      '${dataimporter.last_index_time}'">
      <field column="NAME" name="name" />
      <field column="NAME" name="nameSort" />
      <field column="NAME" name="alphaNameSort" />
    </entity>
    <entity name="feature"
      query="select DESCRIPTION from FEATURE where
      ITEM_ID='${item.ID}'"
      deltaQuery="select ITEM_ID from FEATURE where last_modified
      > '${dataimporter.last_index_time}'"
      parentDeltaQuery="select ID from item where
      ID=${feature.ITEM_ID}">
      <field name="features" column="DESCRIPTION" />
    </entity>
    <entity name="item_category"
      query="select CATEGORY_ID from item_category where
      ITEM_ID='${item.ID}'"
      deltaQuery="select ITEM_ID, CATEGORY_ID from item_category
      where last_modified > '${dataimporter.last_index_time}'"
      parentDeltaQuery="select ID from item where
      ID=${item_category.ITEM_ID}">
      <entity name="category"
        query="select DESCRIPTION from category where ID =
        '${item_category.CATEGORY_ID}'"
      />
    </entity>
  </document>
</dataConfig>
```

The right-hand panel shows the XML response, including status, mode, and configuration details:

```
<response>
  <lst name="responseHeader">
    <int name="status">0</int>
    <int name="QTime">6</int>
  </lst>
  <lst name="initArgs">
    <lst name="defaults">
      <str name="config">db-
      data-config.xml</str>
    </lst>
  </lst>
  <str name="command">full-import</str>
  <str name="mode">debug</str>
  <arr name="documents"/>
  <lst name="verbose-output">
    <lst name="entity:item"/>
  </lst>
  <str name="status">idle</str>
  <str name="importResponse">Configuration
  Re-loaded successfully</str>
  <lst name="statusMessages">

    <str name="Total Documents
    Processed">0</str>
    <str name="Time taken ">0:0:0.3</str>
  </lst>
  <str name="WARNING">
    This response format is experimental. It is likely
    to change in the future.
  </str>
</response>
```

Verbose mode shows details about intermediate steps

If an exception occurred during the run, the console's right-hand panel shows the stacktrace.

Fields produced by the entities or transformers may not be visible in documents if the fields are either not present in the `schema.xml` or there is an explicit `<field>` declaration.

UIMA Integration

You can integrate the Apache Unstructured Information Management Architecture ([UIMA](#)) with Solr. UIMA lets you define custom pipelines of Analysis Engines that incrementally add metadata to your documents as annotations.

For more information about Solr UIMA integration, see <https://wiki.apache.org/solr/SolrUIMA>.

Configuring UIMA

The SolrUIMA UpdateRequestProcessor is a custom update request processor that takes documents being indexed, sends them to a UIMA pipeline, and then returns the documents enriched with the specified metadata. To configure UIMA for Solr, follow these steps:

1. Copy `apache-solr-uima-3.4.0.jar` (under `/apache-solr-3.4.0/dist/`) and its libraries (under `contrib/uima/lib`) to a Solr libraries directory, or set `<lib/>` tags in `solrconfig.xml` appropriately to point to those jar files:

```
<lib dir="../../contrib/uima/lib" />
<lib dir="../../dist/" regex="apache-solr-uima-\d.*\.jar" />
```

2. Modify `schema.xml`, adding your desired metadata fields specifying proper values for type, indexed, stored, and multiValued options. For example:

```
<field name="language" type="string" indexed="true" stored="true"
required="false"/>
<field name="concept" type="string" indexed="true" stored="true"
multiValued="true" required="false"/>
<field name="sentence" type="text" indexed="true" stored="true"
multiValued="true" required="false" />
```

3. Add the following snippet to `solrconfig.xml`:

```
<updateRequestProcessorChain name="uima">
  <processor
class="org.apache.solr.uima.processor.UIMAUpdateRequestProcessorFactory">
  <lst name="uimaConfig">
    <lst name="runtimeParameters">
      <str name="keyword_apikey">VALID_ALCHEMYAPI_KEY</str>
      <str name="concept_apikey">VALID_ALCHEMYAPI_KEY</str>
      <str name="lang_apikey">VALID_ALCHEMYAPI_KEY</str>
      <str name="cat_apikey">VALID_ALCHEMYAPI_KEY</str>
      <str name="entities_apikey">VALID_ALCHEMYAPI_KEY</str>
      <str name="oc_licenseID">VALID_OPENCALAIS_KEY</str>
    </lst>
  </processor>
</updateRequestProcessorChain>
```

```
<str
name="analysisEngine">/org/apache/uima/desc/OverridingParamsExtServicesAE.xml</str>
<!-- Set to true if you want to continue indexing even if text processing fails.
      Default is false. That is, Solr throws RuntimeException and
      never indexed documents entirely in your session. -->
<bool name="ignoreErrors">true</bool>
<!-- This is optional. It is used for logging when text processing fails.
      If logField is not specified, uniqueKey will be used as logField.
<str name="logField">id</str>
-->
<lst name="analyzeFields">
  <bool name="merge">false</bool>
  <arr name="fields">
    <str>text</str>
  </arr>
</lst>
<lst name="fieldMappings">
  <lst name="type">
    <str name="name">org.apache.uima.alchemy.ts.concept.ConceptFS</str>
    <lst name="mapping">
      <str name="feature">text</str>
      <str name="field">concept</str>
    </lst>
  </lst>
  <lst name="type">
    <str name="name">org.apache.uima.alchemy.ts.language.LanguageFS</str>
    <lst name="mapping">
      <str name="feature">language</str>
      <str name="field">language</str>
    </lst>
  </lst>
  <lst name="type">
    <str name="name">org.apache.uima.SentenceAnnotation</str>
    <lst name="mapping">
      <str name="feature">coveredText</str>
      <str name="field">sentence</str>
    </lst>
  </lst>
</lst>
</processor>
<processor class="solr.LogUpdateProcessorFactory" />
<processor class="solr.RunUpdateProcessorFactory" />
</updateRequestProcessorChain>
```

VALID_ALCHEMYAPI_KEY is your AlchemyAPI Access Key. You need to register an AlchemyAPI Access key to use AlchemyAPI services:

<http://www.alchemyapi.com/api/register.html>.

VALID_OPENCALAIS_KEY is your Calais Service Key. You need to register a Calais Service key to use the Calais services: <http://www.opencalais.com/apikey>.

analysisEngine must contain an AE descriptor inside the specified path in the classpath.

analyzeFields must contain the input fields that need to be analyzed by UIMA. If merge=true then their content will be merged and analyzed only once.

Field mapping describes which features of which types should go in a field.

4. In your `solrconfig.xml` replace the existing default UpdateRequestHandler or create a new UpdateRequestHandler:

```
<requestHandler name="/update" class="solr.XmlUpdateRequestHandler">
  <lst name="defaults">
    <str name="update.processor">uima</str>
  </lst>
</requestHandler>
```

Once you are done with the configuration your documents will be automatically enriched with the specified fields when you index them.

Content Streams

When `SolrRequestHandlers` are accessed using path based URLs, the `SolrQueryRequest` object containing the parameters of the request may also contain a list of `ContentStreams` containing bulk data for the request. (The name `SolrQueryRequest` is a bit misleading: it is involved in all requests, regardless of whether it is a query request or an update request.)

Stream Sources

Currently `RequestHandlers` can get content streams in a variety of ways:

- For multipart file uploads, each file is passed as a stream.
- For POST requests where the content-type is not `application/x-www-form-urlencoded`, the raw POST body is passed as a stream.
- The contents of parameter `stream.body` is passed as a stream.
- If remote streaming is enabled, the contents of each `stream.url` and `stream.file` parameters are fetched and passed as a stream.

If the `contentType` is `application/x-www-form-urlencoded`, the full POST body is parsed as parameters and included in the Solr parameters.

By default, curl sends a `contentType="application/x-www-form-urlencoded"` header. If you need to test a `SolrContentHeader` content stream, you will need to set the content type with the `"-H"` flag. For example:

```
curl $URL -H 'Content-type:text/xml; charset=utf-8' --data-binary @$f
```

RemoteStreaming

Remote streaming allows you to send the contents of a URL as a stream to a given `SolrRequestHandler`. You could use remote streaming to send a remote or local file to an update plugin. For security reasons, remote streaming is disabled in the `solrconfig.xml` included in the example directory.

If you enable streaming, be aware that this allows *anyone* to send a request to any URL or local file. If dump is enabled, it will allow anyone to view any file on your system.

```
<!--Make sure your system has authentication before enabling remote streaming!-->  
<requestParsers enableRemoteStreaming="true" multipartUploadLimitInKB="2048" />
```

Debugging Requests

The example `solrconfig.xml` includes a "dump" RequestHandler:

```
<requestHandler name="/debug/dump" class="solr.DumpRequestHandler" />
```

This handler simply outputs the contents of the `SolrQueryRequest` using the specified writer type `wt`. This is a useful tool to help understand what streams are available to the RequestHandlers.

Searching

This section describes how Solr works with search requests. It covers the following topics:

[Overview of Searching in Solr](#): Conceptual information about searching with Solr.

[Relevance](#): Conceptual information about relevance in search results.

[Query Syntax and Parsing](#): A brief conceptual overview of query syntax and parsing.

[The DisMax Query Parser](#): Detailed information about Solr's DisMax query parser.

[The Extended DisMax Query Parser](#): Detailed information about Solr's Extended DisMax (eDisMax) Query Parser.

[The Standard Query Parser](#): Detailed information about the standard Lucene query parser.

[Common Query Parameters](#): Detailed information about the common query parameters in Solr.

[Local Parameters in Queries](#): Detailed information about arguments specific to a particular query parameter.

[Function Queries](#): Detailed information about parameters for generating relevancy scores using values from one or more numeric fields.

[Highlighting](#): Detailed information about Solr's highlighting utilities.

[MoreLikeThis](#): Detailed information about Solr's similar results query component.

[Faceting](#): Detailed information about categorizing search results based on indexed terms.

[Result Grouping](#): Detailed information about grouping results based on common field values.

[Spell Checking](#): Detailed information about Solr's spelling checker.

[Suggester](#): Detailed information about Suggester, Solr's powerful autosuggest component.

[Spatial Search](#): Detailed information about Solr's spatial search capabilities.

[The Terms Component](#): Detailed information about accessing indexed terms and the documents that include them.

[The Term Vector Component](#): Detailed information about returning term information about specific documents.

[The Stats Component](#): Detailed information about returning information from numeric fields within a document set.

[Response Writers](#): Detailed information about configuring and using Solr's response writers.

Overview of Searching in Solr

Solr offers a rich, flexible set of features for search. To understand the extent of this flexibility, it's helpful to begin with an overview of the steps and components involved in a Solr search.

When a user runs a search in Solr, the search query is processed by a **request handler**. A request handler is a Solr plug-in that defines the logic to be used when Solr processes a request. Solr supports a variety of request handlers. Some are designed for processing search queries, while others manage tasks such as index replication.

Search applications select a particular request handler by default. In addition, applications can be configured to allow users to override the default selection in preference of a different request handler.

To process a search query, a request handler calls a **query parser**, which interprets the terms and parameters of a query. Different query parsers support different syntax. The default query parser is the [DisMax](#) query parser. Solr also includes an earlier "standard" (Lucene) query parser, and an [Extended DisMax](#) (eDisMax) query parser. The [standard](#) query parser's syntax allows for greater precision in searches, but the DisMax query parser is much more tolerant of errors. The DisMax query parser is designed to provide an experience similar to that of popular search engines such as Google, which rarely display syntax errors to users. The Extended DisMax query parser is an improved version of DisMax that handles the full Lucene query syntax while still tolerating syntax errors. It also includes several additional features.

In addition, there are [common query parameters](#) that are accepted by all query parsers.

Input to a query parser can include:

- search strings—that is, *terms* to search for in the index
- *parameters for fine-tuning the query* by increasing the importance of particular strings or fields, by applying Boolean logic among the search terms, or by excluding content from the search results
- *parameters for controlling the presentation of the query response*, such as specifying the order in which results are to be presented or limiting the response to particular fields of the search application's schema.

Search parameters may also specify a **query filter**. As part of a search response, a query filter runs a query against the entire index and caches the results. Because Solr allocates a separate cache for filter queries, the strategic use of filter queries can improve search performance. (Despite their similar names, query filters are not related to analysis filters. Query filters perform queries at search time against data already in the index, while analysis filters, such as Tokenizers, parse content for indexing, following specified rules).

A search query can request that certain terms be highlighted in the search response; that is, the selected terms will be displayed in colored boxes so that they "jump out" on the screen of search results. **Highlighting** can make it easier to find relevant passages in long documents returned in a search. Solr supports multi-term highlighting. Solr includes a rich set of search parameters for controlling how terms are highlighted.

Search responses can also be configured to include **snippets** (document excerpts) featuring highlighted text. Popular search engines such as Google and Yahoo! return snippets in their search results: 3-4 lines of text offering a description of a search result.

To help users zero in on the content they're looking for, Solr supports two special ways of grouping search results to aid further exploration: faceting and clustering.

Faceting is the arrangement of search results into categories (which are based on indexed terms). Within each category, Solr reports on the number of hits for relevant term, which is called a facet constraint. Faceting makes it easy for users to explore search results on sites such as movie sites and product review sites, where there are many categories and many items within a category.

The image below shows an example of faceting from the CNET Web site, which was the first site to use Solr.

The image shows a search results page for "Digital cameras" with a "Refine your results" section. The facets are:

- Manufacturer:** Canon USA (5), Sony (2), Nikon (2), Olympus (6), Pentax (2)
- Resolution:** 6 megapixels (3), 8 megapixels and up (14)
- Zoom range:** 3X to 4X (11), 8X to 12X (1)
- More:** LCD size, Image stabilizer, Flash memory, Still image format, Maximum ISO

Below the facets, there is a "you selected:" section with filters for "\$400 - \$500", "SLR", and "remove all". The main results list shows "17 results" and a "Regular search results list" with page numbers "1 2 next". The first result is "Canon EOS Rebel XS (silver, with 18-55mm lens)" priced at "\$459 to \$699 at 15 stores".

Callouts explain that "Manufacturer is a facet, a way of categorizing the results", "Canon, Sony, and Nikon are constraints, or facet values", "The breadcrumb trail shows what constraints have already been applied and allows for their removal", and "The facet count or constraint count shows how many results match each value".

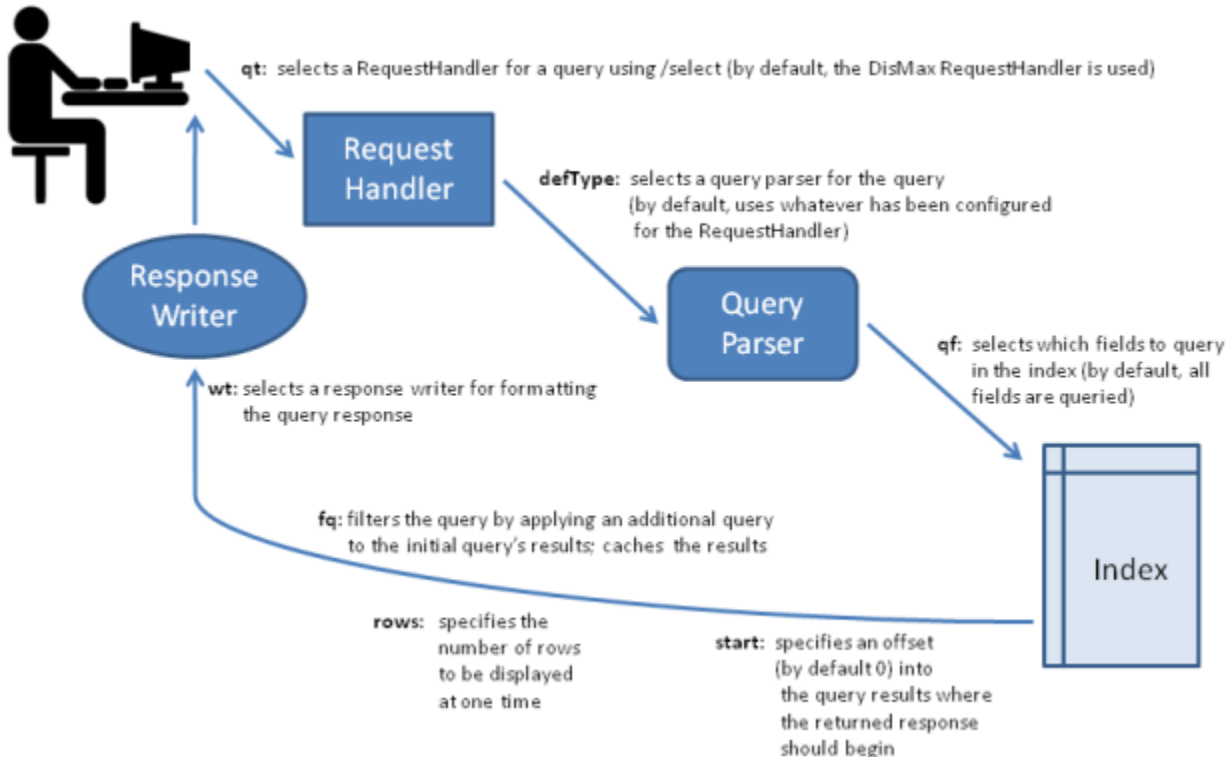

Faceting makes use of fields defined when the search applications were indexed. In the example above, these fields include categories of information that are useful for describing digital cameras: manufacturer, resolution, and zoom range.

Clustering groups search results by similarities discovered when a search is executed, rather than when content is indexed. The results of clustering often lack the neat hierarchical organization found in faceted search results, but clustering can be useful nonetheless. It can reveal unexpected commonalities among search results, and it can help users rule out content that isn't pertinent to what they're really searching for.

Solr also supports a feature called [MoreLikeThis](#), which enables users to submit new queries that focus on particular terms returned in an earlier query. MoreLikeThis queries can make use of faceting or clustering to provide additional aid to users.

A Solr component called a **response writer** manages the final presentation of the query response. Solr includes a variety of response writers, including an [XML Response Writer](#) and a [JSON Response Writer](#).

The diagram below summarizes some key elements of the search process.

The Velocity Search UI

Solr includes an example search UI based on the [VelocityResponseWriter](#) (also known as Solritas) that demonstrates several useful features, such as searching, faceting, highlighting, autocomplete, and geospatial searching.

You can access the Velocity Search UI here: <http://localhost:8983/solr/browse>

For more information about the Velocity Search UI, see <https://wiki.apache.org/solr/VelocityEngine>.

Relevance

Relevance is the degree to which a query response satisfies a user who is searching for information.

The relevance of a query response depends on the context in which the query was performed. A single search application may be used in different contexts by users with different needs and expectations. For example, a search engine of climate data might be used by a university researcher studying long-term climate trends, a farmer interested in calculating the likely date of the last frost of spring, a civil engineer interested in rainfall patterns and the frequency of floods, and a college student planning a vacation to a region and wondering what to pack. Because the motivations of these users vary, the relevance of any particular response to a query will vary as well.

How comprehensive should query responses be? Like relevance in general, the answer to this question depends on the context of a search. The cost of *not* finding a particular document in response to a query is high in some contexts, such as a legal e-discovery search in response to a subpoena, and quite low in others, such as a search for a cake recipe on a Web site with dozens or hundreds of cake recipes. When configuring Solr, you should weigh comprehensiveness against other factors such as timeliness and ease-of-use.

The e-discovery and recipe examples demonstrate the importance of two concepts related to relevance:

- **Precision** is the percentage of documents in the returned results that are relevant.
- **Recall** is the percentage of relevant results returned out of all relevant results in the system. Obtaining perfect recall is trivial: simply return every document in the collection for every query.

Returning to the examples above, it's important for an e-discovery search application to have 100% recall returning all the documents that are relevant to a subpoena. It's far less important that a recipe application offer this degree of precision, however. In some cases, returning too many results in casual contexts could overwhelm users. In some contexts, returning fewer results that have a higher likelihood of relevance may be the best approach.

Using the concepts of precision and recall, it's possible to quantify relevance across users and queries for a collection of documents. A perfect system would have 100% precision and 100% recall for every user and every query. In other words, it would retrieve all the relevant documents and nothing else. In practical terms, when talking about precision and recall in real systems, it is common to focus on precision and recall at a certain number of results, the most common (and useful) being ten results.

Through faceting, query filters, and other search components, a Solr application can be configured with the flexibility to help users fine-tune their searches in order to return the most relevant results for users. That is, Solr can be configured to balance precision and recall to meet the needs of a particular user community.

The configuration of a Solr application should take into account:

- the needs of the application's various users (which can include ease of use and speed of response, in addition to strictly informational needs)
- the categories that are meaningful to these users in their various contexts (e.g., dates, product categories, or regions)
- any inherent relevance of documents (e.g., it might make sense to ensure that an official product description or FAQ is always returned near the top of the search results)
- whether or not the age of documents matters significantly (in some contexts, the most recent documents might always be the most important)

Keeping all these factors in mind, it's often helpful in the planning stages of a Solr deployment to sketch out the types of responses you think the search application should return for sample queries. Once the application is up and running, you can employ a series of testing methodologies, such as focus groups, in-house testing, [TREC](#) tests and A/B testing to fine tune the configuration of the application to best meet the needs of its users.

For more information about relevance, see Grant Ingersoll's tech article [Debugging Search Application Relevance Issues](#) which is available on the Lucid Imagination Web site.

Query Syntax and Parsing

Solr supports several query parsers, offering search application designers great flexibility in controlling how queries are parsed.

This section explains how to specify the query parser to be used. It also describes the syntax and features supported by the main query parsers included with Solr: the Standard Query Parser, the DisMax query parser, and the Extended DisMax (eDisMax) query parser.

For more detailed information about the many query parsers available in Solr, see <https://wiki.apache.org/solr/SolrQuerySyntax>.

Common Query Parameters

The table below summarizes Solr's common query parameters, which are supported by the [Standard](#), [DisMax](#), and [eDisMax](#) Request Handlers.

Lucid Imagination strongly recommends that any future SolrRequestHandlers support these parameters, as well.

Parameter	Description
defType	Selects the query parser to be used to process the query.
sort	Sorts the response to a query in either ascending or descending order based on the response's score or another specified characteristic.
start	Specifies an offset (by default, 0) into the responses at which Solr should begin displaying content.
rows	Controls how many rows of responses are displayed at a time (default value: 10)
fq	Applies a filter query to the search results.
fl	Limits the query's responses to a listed set of fields.
debugQuery	Causes Solr to include additional debugging information in the response, including "explain" information for each of the documents returned. Note that this parameter takes effect if it is present, regardless of its setting.
explainOther	Allows clients to specify a Lucene query to identify a set of documents. If non-blank, the explain info of each document which matches this query, relative to the main query (specified by the q parameter) will be returned along with the rest of the debugging information.

<code>timeAllowed</code>	Defines the time allowed for the query to be processed. If the time elapses before the query response is complete, partial information may be returned.
<code>omitHeader</code>	Excludes the header from the returned results, if set to true. The header contains information about the request, such as the time the request took to complete. The default is false.
<code>wt</code>	Specifies the Response Writer to be used to format the query response.
<code>cache=false</code>	By default, Solr caches the results of all queries and filter queries. Set <code>cache=false</code> to disable caching of the results of a query.

The following sections describe these parameters in detail.

The defType Parameter

The `defType` parameter selects the query parser that Solr should use to process the request. For example:

```
defType=dismax
```

In Solr 1.3 and later, the query parser is set to `dismax` by default.

The sort Parameter

The `sort` parameter arranges search results in either ascending (`asc`) or descending (`desc`) order. The parameter can be used with either numerical or alphabetical content.

Solr can sort query responses according to document scores or the value of any indexed field with a single value (that is, any field whose attributes in `schema.xml` include `multiValued="false"` and `indexed="true"`), provided that:

- the field is non-tokenized (that is, the field has no analyzer and its contents have been been parsed into tokens, which would make the sorting inconsistent), or
- the field uses an analyzer (such as the `KeywordTokenizer`) that produces only a single term.

If you want to be able to sort on a field whose contents you want to tokenize to facilitate searching, use the `<copyField>` directive in the `schema.xml` file to clone the field. Then search on the field and sort on its clone.

The table explains how Solr responds to various settings of the `sort` parameter.

Example of a sort Parameter	Result

	If the sort parameter is omitted, sorting is performed as though the parameter were set to <code>score desc</code> .
<code>score desc</code>	Sorts in descending order from the highest score to the lowest score.
<code>price asc</code>	Sorts in ascending order of the price field
<code>inStock desc, price asc</code>	Sorts by the contents of the <code>inStock</code> field in descending order, then within those results sorts in ascending order by the contents of the price field.

Regarding the sort parameter's arguments:

- A sort ordering must include a field name (or `score` as a pseudo field), followed by whitespace (escaped as `+` or `%20` in URL strings), followed by a sort direction (`asc` or `desc`).
- Multiple sort orderings can be separated by a comma, using this syntax: `sort=<field name> <direction>[,<field name> <direction>]...`

The start Parameter

When specified, the `start` parameter specifies an offset into a query's result set and instructs Solr to begin displaying results from this offset.

The default value is "0". In other words, by default, Solr returns results without an offset, beginning where the results themselves begin.

Setting the `start` parameter to some other number, such as 3, causes Solr to skip over the preceding records and start at the document identified by the offset.

You can use the `start` parameter this way for paging. For example, if the `rows` parameter is set to 10, you could display three successive pages of results by setting `start` to 0, then re-issuing the same query and setting `start` to 10, then issuing the query again and setting `start` to 20.

The rows Parameter

You can use the `rows` parameter to paginate results from a query. The parameter specifies the maximum number of documents from the complete result set that Solr should return to the client at one time.

The default value is 10. That is, by default, Solr returns 10 documents at a time in response to a query.

The fq (Filter Query) Parameter

The `fq` parameter defines a query that can be used to restrict the superset of documents that can be returned, without influencing score. It can be very useful for speeding up complex queries, since the queries specified with `fq` are cached independently of the main query. When a later query uses the same filter, there's a cache hit, and filter results are returned quickly from the cache.

When using the `fq` parameter, keep in mind the following:

- The `fq` parameter can be specified multiple times in a query. Documents will only be included in the result if they are in the intersection of the document sets resulting from each instance of the parameter. In the example below, only documents which have a popularity greater than 10 and have a section of 0 will match.

```
fq=popularity:[10 TO *]
& fq=section:0
```

- Filter queries can involve complicated Boolean queries. The above example could also be written as a single `fq` with two mandatory clauses like so:

```
fq=+popularity:[10 TO *] +section:0
```

- The document sets from each filter query are cached independently. Thus, concerning the previous examples: use a single `fq` containing two mandatory clauses if those clauses appear together often, and use two separate `fq` parameters if they are relatively independent. (To learn about tuning cache sizes and making sure a filter cache actually exists, see [The Well-Configured Solr Instance](#).)
- As with all parameters: special characters in an URL need to be properly escaped and encoded as hex values. Online tools are available to help you with URL-encoding. For example: http://netzreport.googlepages.com/online_tool_for_url_en_decoding.html.

The fl (Field List) Parameter

The `fl` parameter limits the information included in a query response to a specified list of fields. The fields need to have been indexed as stored for this parameter to work correctly.

The field list can be specified as a space-separated or comma-separated list of field names. The string "score" can be used to indicate that the score of each document for the particular query should be returned as a field. The wildcard character "*" selects all the stored fields in a document.

Field List	Result
id name price	Return only the id, name, and price fields.

id,name,price	Return only the id, name, and price fields.
id name, price	Return only the id, name, and price fields.
id score	Return the id field and the score.
*	Return all the fields in each document. This is the default value of the fl parameter.
* score	Return all the fields in each document, along with each field's score.

As noted in the table above, the default value is "*".

The debugQuery Parameter

If the `debugQuery` parameter is present (regardless of its value), then additional debugging information will be included in the response, including "explain" info for each of the documents returned. (The "explain" info tells you why your query matched and indicates which parts of the query contributed to the overall score.) This debugging info is meant for human consumption. Its XML format could change in future Solr releases.

The default behavior is not to include debugging information.

The explainOther Parameter

The `explainOther` parameter specifies a Lucene query in order to identify a set of documents. If this parameter is included and is set to a non-blank value, the query will return debugging information, along with the "explain info" of each document that matches the Lucene query, relative to the main query (which is specified by the `q` parameter). For example:

```
q=supervillians&debugQuery=on&explainOther=id:juggernaut
```

The query above allows you to examine the scoring explain info of the top matching documents, compare it to the explain info for documents matching `id:juggernaut`, and determine why the rankings are not as you expect.

The default value of this parameter is blank, which causes no extra "explain info" to be returned.

The timeAllowed Parameter

This parameter specifies the amount of time, in milliseconds, allowed for a search to complete. If this time expires before the search is complete, any partial results will be returned.

The omitHeader Parameter

This parameter may be set to either true or false.

If set to true, this parameter excludes the header from the returned results. The header contains information about the request, such as the time it took to complete. The default value for this parameter is false.

The wt Parameter

The `wt` parameter selects the Response Writer that Solr should use to format the query's response. For detailed descriptions of Response Writers, see [Response Writers](#).

The cache=false Parameter

Solr caches the results of all queries and filter queries by default. To disable result caching, set the `cache=false` parameter.

You can also use the `cost` option to control the order in which non-cached filter queries are evaluated. This allows you to order less expensive non-cached filters before expensive non-cached filters.

For very high cost filters, if `cache=false` and `cost>=100` and the query implements the `PostFilter` interface, a Collector will be requested from that query and used to filter documents after they have matched the main query and all other filter queries. There can be multiple post filters; they are also ordered by cost.

For example:

```
// normal function range query used as a filter, all matching documents generated up
// front and cached
fq={!frange l=10 u=100}mul(popularity,price)

// function range query run in parallel with the main query like a traditional lucene
// filter
fq={!frange l=10 u=100 cache=false}mul(popularity,price)

// function range query checked after each document that already matches the query and
// all other filters.
    Good for really expensive function queries.
fq={!frange l=10 u=100 cache=false cost=100}mul(popularity,price)
```

The Standard Query Parser

Before Solr 1.3, the Standard Request Handler called the standard query parser as the default query parser. In versions since Solr 1.3, the Standard Request Handler calls the DisMax query parser as the default query parser. You can configure Solr to call the standard query parser instead, if you like.

The advantage of the standard query parser is that it enables users to specify very precise queries. The disadvantage is that it's less tolerant of syntax errors than the [DisMax](#) query parser. The DisMax query parser is designed to throw as few errors as possible.

Topics covered in this section:

- [Standard Query Parser Parameters](#)
- [The Standard Query Parser's Response](#)
- [Specifying Terms for the Standard Query Parser](#)
- [Specifying Fields in a Query to the Standard Query Parser](#)
- [Boolean Operators Supported by the Standard Query Parser](#)
- [Grouping Terms to Form Subqueries](#)
- [Differences between Lucene Query Parser and the Solr Standard Query Parser](#)

Standard Query Parser Parameters

In addition to the [Common Query Parameters](#), [Faceting Parameters](#), [Highlighting Parameters](#), and [MoreLikeThis Parameters](#), the standard query parser supports the parameters described in the table below.

Parameter	Description
q	Defines a query using standard query syntax. This parameter is mandatory.
q.op	Specifies the default operator for query expressions, overriding the default operator specified in the <code>schema.xml</code> file. Possible values are "AND" or "OR".
df	Specifies a default field, overriding the definition of a default field in the <code>schema.xml</code> file.

Default parameter values are specified in `solrconfig.xml`, or overridden by query-time values in the request.

The Standard Query Parser's Response

By default, the response from the standard query parser contains one `<result>` block, which is unnamed. If the [debugQuery](#) parameter is used, then an additional `<lst>` block will be returned, using the name "debug". This will contain useful debugging info, including the original query string, the parsed query string, and explain info for each document in the `<result>` block. If the [explainOther](#) parameter is also used, then additional explain info will be provided for all the documents matching that query.

Sample Responses

This section presents examples of responses from the standard query parser.

The URL below submits a simple query and requests the XML Response Writer to use indentation to make the XML response more readable.

```
http://yourhost.tld:9999/solr/select?q=id:SP2514N&version=2.1&indent=1
```

Results:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
<responseHeader><status>0</status><QTime>1</QTime></responseHeader>
<result numFound="1" start="0">
  <doc>
    <arr name="cat"><str>electronics</str><str>hard drive</str></arr>
    <arr name="features"><str>7200RPM, 8MB cache, IDE Ultra ATA-133</str>
      <str>NoiseGuard, SilentSeek technology, Fluid Dynamic Bearing (FDB)
motor</str></arr>
    <str name="id">SP2514N</str>
    <bool name="inStock">true</bool>
    <str name="manu">Samsung Electronics Co. Ltd.</str>
    <str name="name">Samsung SpinPoint P120 SP2514N - hard drive - 250 GB - ATA-133</str>
    <int name="popularity">6</int>
    <float name="price">92.0</float>
    <str name="sku">SP2514N</str>
  </doc>
</result>
</response>
```

Here's an example of a query with a limited field list.

```
http://yourhost.tld:9999/solr/select?q=id:SP2514N&version=2.1&indent=1&fl=id+name
```

Results:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
<responseHeader><status>0</status><QTime>2</QTime></responseHeader>
<result numFound="1" start="0">
  <doc>
    <str name="id">SP2514N</str>
    <str name="name">Samsung SpinPoint P120 SP2514N - hard drive - 250 GB - ATA-133</str>
  </doc>
</result>
</response>
```

Specifying Terms for the Standard Query Parser

A query to the standard query parser is broken up into terms and operators. There are two types of terms: single terms and phrases.

- A single term is a single word such as "test" or "hello"
- A phrase is a group of words surrounded by double quotes such as "hello dolly"

Multiple terms can be combined together with Boolean operators to form more complex queries (as described below).

It is important that the analyzer used for queries parses terms and phrases in a way that is consistent with the way the analyzer used for indexing parses terms and phrases; otherwise, searches may produce unexpected results.

Term Modifiers

Solr supports a variety of term modifiers that add flexibility or precision, as needed, to searches. These modifiers include wildcard characters, characters for making a search "fuzzy" or more general, and so on. The sections below describe these modifiers in detail.

Wildcard Searches

Solr's standard query parser supports single and multiple character wildcard searches within single terms. Wildcard characters can be applied to single terms, but not to search phrases.

Wildcard Search Type	Special Character	Example
Single character (matches a single character)	?	The search string <code>te?t</code> would match both <code>test</code> and <code>text</code> .

Multiple characters (matches zero or more sequential characters)	*	<p>The wildcard search:</p> <p>tes*</p> <p>would match test, testing, and tester.</p> <p>You can also use wildcard characters in the middle of a term. For example:</p> <p>te*t</p> <p>would match test and text.</p> <p>*est</p> <p>would match pest and test.</p>
--	---	---

As of Solr 1.4, you can use a * or ? symbol as the first character of a search with the standard query parser.

Fuzzy Searches

Solr's standard query parser supports fuzzy searches based on the Levenshtein Distance or Edit Distance algorithm. Fuzzy searches discover terms that are similar to a specified term without necessarily being an exact match. To perform a fuzzy search, use the tilde ~ symbol at the end of a single-word term. For example, to search for a term similar in spelling to "roam," use the fuzzy search:

```
roam~
```

This search will match terms like foam and roams. It will also match the word "roam" itself.

An optional, additional parameter specifies the degree of similarity required for a match in a fuzzy search. The value must be between 0 and 1. When set closer to 1, the optional parameter causes only terms with a higher similarity to be matched. For example, the search below requires a high degree of similarity to the term "roam" in order for Solr to return a match:

```
roam~0.8
```

If this numerical parameter is omitted, Lucene performs the search as though the parameter were set to 0.5. The sample query above is not very scalable. Upon parsing this query will check the quasi-edit distance for every term in the index. As a result, this query is practical for only very small indexes.

In many cases, stemming (reducing terms to a common stem) can produce similar effects to fuzzy searches and wildcard searches.

Proximity Searches

A proximity search looks for terms that are within a specific distance from one another.

To perform a proximity search, add the tilde character ~ and a numeric value to the end of a search phrase. For example, to search for a "apache" and "jakarta" within 10 words of each other in a document, use the search:

```
"jakarta apache"~10
```

The distance referred to here is the number of term movements needed to match the specified phrase. In the example above, if "apache" and "jakarta" were 10 spaces apart in a field, but "apache" appeared before "jakarta", more than 10 term movements would be required to move the terms together and position "apache" to the right of "jakarta" with a space in between.

Range Searches

A range search specifies a range of values for a field (a range with an upper bound and a lower bound). The query matches documents whose values for the specified field or fields fall within the range. Range queries can be inclusive or exclusive of the upper and lower bounds. Sorting is done lexicographically, except on numeric fields. For example, the range query below matches all documents whose `mod_date` field has a value between 20020101 and 20030101, inclusive.

```
mod_date:[20020101 TO 20030101]
```

Range queries are not limited to date fields or even numerical fields. You could also use range queries with non-date fields:

```
title:{Aida TO Carmen}
```

This will find all documents whose titles are between Aida and Carmen, but not including Aida and Carmen.

The brackets around a query determine its inclusiveness.

- Square brackets [] denote an inclusive range query that matches values including the upper and lower bound.

- Curly brackets { } denote an exclusive range query that matches values between the upper and lower bounds, but excluding the upper and lower bounds themselves.

Boosting a Term with ^

Lucene/Solr provides the relevance level of matching documents based on the terms found. To boost a term use the caret symbol ^ with a boost factor (a number) at the end of the term you are searching. The higher the boost factor, the more relevant the term will be.

Boosting allows you to control the relevance of a document by boosting its term. For example, if you are searching for

"jakarta apache" and you want the term "jakarta" to be more relevant, you can boost it by adding the ^ symbol along with the boost factor immediately after the term. For example, you could type:

```
jakarta^4 apache
```

This will make documents with the term jakarta appear more relevant. You can also boost Phrase Terms as in the example:

```
"jakarta apache"^4 "Apache Lucene"
```

By default, the boost factor is 1. Although the boost factor must be positive, it can be less than 1 (for example, it could be 0.2).

Specifying Fields in a Query to the Standard Query Parser

Data indexed in Solr is organized in fields, which are defined in the Solr `schema.xml` file. Searches can take advantage of fields to add precision to queries. For example, you can search for a term only in a specific field, such as a title field.

The `schema.xml` file defines one field as a default field. If you do not specify a field in a query, Solr searches only the default field. Alternatively, you can specify a different field or a combination of fields in a query.

To specify a field, type the field name followed by a colon ":" and then the term you are searching for within the field.

For example, suppose an index contains two fields, title and text, and that text is the default field. If you want to find a document called "The Right Way" which contains the text "don't go this way," you could include either of the following terms in your search query:

```
title:"The Right Way" AND text:go
```

```
title:"Do it right" AND go
```

Since text is the default field, the field indicator is not required; hence the second query above omits it.

The field is only valid for the term that it directly precedes, so the query `title:Do it right` will find only "Do" in the title field. It will find "it" and "right" in the default field (in this case the text field).

Boolean Operators Supported by the Standard Query Parser

Boolean operators allow you to apply Boolean logic to queries, requiring the presence or absence of specific terms or conditions in fields in order to match documents. The table below summarizes the Boolean operators supported by the standard query parser.

Boolean Operator	Alternative Symbol	Description
AND	&&	Requires both terms on either side of the Boolean operator to be present for a match.
NOT	!	Requires that the following term not be present.
OR		Requires that either term (or both terms) be present for a match.
	+	Requires that the following term be present.
	-	Prohibits the following term (that is, matches on fields or documents that do not include that term). The - operator is functional similar to the Boolean operator !. Because it's used by popular search engines such as Google, it may be more familiar to some user communities.

Boolean operators allow terms to be combined through logic operators. Lucene supports AND, "+", OR, NOT and "-" as Boolean operators.

When specifying Boolean operators with keywords such as AND or NOT, the keywords must appear in all uppercase.

The standard query parser supports all the Boolean operators listed in the table above. The DisMax query parser supports only + and -.

The OR operator is the default conjunction operator. This means that if there is no Boolean operator between two terms, the OR operator is used. The OR operator links two terms and finds a matching document if either of the terms exist in a document. This is equivalent to a union using sets. The symbol || can be used in place of the word OR.

In the `schema.xml` file, you can specify which symbols can take the place of Boolean operators such as OR. To search for documents that contain either "jakarta apache" or just "jakarta," use the query:

```
"jakarta apache" jakarta
```

or

```
"jakarta apache" OR jakarta
```

The Boolean Operator +

The + symbol (also known as the "required" operator) requires that the term after the + symbol exist somewhere in a field in at least one document in order for the query to return a match.

For example, to search for documents that must contain "jakarta" and that may or may not contain "lucene," use the following query:

```
+jakarta lucene
```

This operator is supported by both the standard query parser and the DisMax query parser.

The Boolean Operator AND (&&)

The AND operator matches documents where both terms exist anywhere in the text of a single document. This is equivalent to an intersection using sets. The symbol && can be used in place of the word AND.

To search for documents that contain "jakarta apache" and "Apache Lucene," use either of the following queries:

```
"jakarta apache" AND "Apache Lucene"
```

```
"jakarta apache" && "Apache Lucene"
```

The Boolean Operator NOT (!)

The NOT operator excludes documents that contain the term after NOT. This is equivalent to a difference using sets. The symbol ! can be used in place of the word NOT.

The following queries search for documents that contain the phrase "jakarta apache" but do not contain the phrase "Apache Lucene":

```
"jakarta apache" NOT "Apache Lucene"
```

```
"jakarta apache" ! "Apache Lucene"
```

The Boolean Operator -

The - symbol or "prohibit" operator excludes documents that contain the term after the - symbol.

For example, to search for documents that contain "jakarta apache" but not "Apache Lucene," use the following query:

```
"jakarta apache" -"Apache Lucene"
```

Escaping Special Characters

Solr gives the following characters special meaning when they appear in a query:

```
+ - && || ! ( ) { } [ ] ^ " ~ * ? : \
```

To make Solr interpret any of these characters literally, rather as a special character, precede the character with a backslash character \. For example, to search for (1+1):2 without having Solr interpret the plus sign and parentheses as special characters for formulating a subquery with two terms, escape the characters by preceding each one with a backslash:

```
\(1\+1\)\:2
```

Grouping Terms to Form Subqueries

Lucene/Solr supports using parentheses to group clauses to form subqueries. This can be very useful if you want to control the Boolean logic for a query.

The query below searches for either "jakarta" or "apache" and "website":

```
(jakarta OR apache) AND website
```

This adds precision to the query, requiring that the term "website" exist, along with either term "jakarta" and "apache."

Grouping Clauses within a Field

To apply two or more Boolean operators to a single field in a search, group the Boolean clauses within parentheses. For example, the query below searches for a title field that contains both the word "return" and the phrase "pink panther":

```
title:(+return +"pink panther")
```

Differences between Lucene Query Parser and the Solr Standard Query Parser

Solr's standard query parser differs from the Lucene Query Parser in the following ways:

- A * may be used for either or both endpoints to specify an open-ended range query
 - `field:[* TO 100]` finds all field values less than or equal to 100
 - `field:[100 TO *]` finds all field values greater than or equal to 100
 - `field:[* TO *]` matches all documents with the field
- Pure negative queries (all clauses prohibited) are allowed (only as a top-level clause)
 - `-inStock:false` finds all field values where inStock is not false
 - `-field:[* TO *]` finds all documents without a value for field
- A hook into FunctionQuery syntax. You'll need to use quotes to encapsulate the function if it includes parentheses, as shown in the second example below
 - `val :myfield`
 - `val : "recip(rord(myfield),1,2,3)"`
- Nested query support for any type of query parser. Quotes will often be necessary to encapsulate the nested query if it contains reserved characters.
 - `query : "{!dismax qf=myfield}how now brown cow"`

The standard Solr query parser also differs from earlier (pre-2.9) versions of the Lucene query parser in this way:

- Range queries `[a TO z]`, prefix queries `a*`, and wildcard queries `a*b` are constant-scoring (all matching documents get an equal score). The scoring factors TF, IDF, index boost, and coord are not used. There is no limitation on the number of terms that match (as there was in past versions of Lucene).

Specifying Dates and Times

If you use the Solr "DateField" type, any queries on those fields (typically range queries) should use the TrieDate Field. In previous releases, you would use the complete ISO 8601 date syntax that "DateField" supports, or the Lucene/Solr DateMathParser's syntax to get relative dates.

Here are some examples of valid parameters using syntax appropriate for the DateField type:

- `timestamp:[*TO NOW]`
- `createdate:[1976-03-06T23:59:59.999Z TO *]`
- `createdate:[1995-12-31T23:59:59.999Z TO 2007-03-06T00:00:00Z]`
- `pubdate:[NOW-1YEAR/DAY TO NOW/DAY+1DAY]`
- `createdate:[1976-03-06T23:59:59.999Z TO 1976-03-06T23:59:59.999Z+1YEAR]`
- `createdate:[1976-03-06T23:59:59.999Z/YEAR TO 1976-03-06T23:59:59.999Z]`

The DisMax Query Parser

The DisMax query parser is designed to process simple phrases (without complex syntax) entered by users and to search for individual terms across several fields using different weighting (boosts) based on the significance of each field. Additional options enable users to influence the score based on rules specific to each use case (independent of user input).

In general, the DisMax query parser's interface is more like that of Google than the interface of the "standard" Solr request handler. This similarity makes DisMax the appropriate query parser for many consumer applications. It accepts a simple syntax, and it rarely produces error messages.

The DisMax query parser supports an extremely simplified subset of the Lucene QueryParser syntax. As in Lucene, quotes can be used to group phrases, and +/- can be used to denote mandatory and optional clauses. All other Lucene query parser special characters (except AND and OR) are escaped to simplify the user experience. The DisMax query parser takes responsibility for building a good query from the user's input using Boolean clauses containing DisMax queries across fields and boosts specified by the user. It also lets the Solr administrator provide additional boosting queries, boosting functions, and filtering queries to artificially affect the outcome of all searches. These options can all be specified as default parameters for the handler in the `solrconfig.xml` file or overridden in the Solr query URL.

Interested in the technical concept behind the DisMax name? DisMax stands for Maximum Disjunction. Here's a definition of a Maximum Disjunction or "DisMax" query:

A query that generates the union of documents produced by its subqueries, and that scores each document with the maximum score for that document as produced by any subquery, plus a tie breaking increment for any additional matching subqueries.

Whether or not you remember this explanation, do remember that the DisMax request handler was primarily designed to be easy to use and to accept almost any input without returning an error.

DisMax Parameters

In addition to the common request parameter, highlighting parameters, and simple facet parameters, the DisMax query parser supports the parameters described below. Like the standard query parser, the DisMax query parser allows default parameter values to be specified in `solrconfig.xml`, or overridden by query-time values in the request.

Parameter	Description
<code>q</code>	Defines the raw input strings for the query.
<code>q.alt</code>	Calls the standard query parser and defines query input strings, when the <code>q</code> parameter is not used.
<code>qf</code>	Query Fields: specifies the fields in the index on which to perform the query.
<code>mm</code>	Minimum "Should" Match: specifies a minimum number of fields that must match in a query.
<code>pf</code>	Phrase Fields: boosts the score of documents in cases where all of the terms in the <code>q</code> parameter appear in close proximity.

<code>ps</code>	Phrase Slop: specifies the number of positions two terms can be apart in order to match the specified phrase.
<code>qs</code>	Query Phrase Slop: specifies the number of positions two terms can be apart in order to match the specified phrase. Used specifically with the <code>qf</code> parameter.
<code>tie</code>	Tie Breaker: specifies a float value (which should be something much less than 1) to use as tiebreaker in DisMax queries.
<code>bq</code>	Boost Query: specifies a factor by which a term or phrase should be "boosted" in importance when considering a match.
<code>bf</code>	Boost Functions: specifies functions to be applied to boosts. (See for details about function queries.)

The sections below explain these parameters in detail.

The `q` Parameter

The `q` parameter defines the main "query" constituting the essence of the search. The parameter supports raw input strings provided by users with no special escaping. The `+` and `-` characters are treated as "mandatory" and "prohibited" modifiers for terms. Text wrapped in balanced quote characters (for example, "San Jose") is treated as a phrase. Any query containing an odd number of quote characters is evaluated as if there were no quote characters at all.

 The `q` parameter does not support wildcard characters such as `*`.

The `q.alt` Parameter

If specified, the `q.alt` parameter defines a query (which by default will be parsed using standard query parsing syntax) when the main `q` parameter is not specified or is blank. The `q.alt` parameter comes in handy when you need something like a query to match all documents (don't forget `&rows=0` for that one!) in order to get collection-wise faceting counts.

The `qf` (Query Fields) Parameter

The `qf` parameter introduces a list of fields, each of which is assigned a boost factor to increase or decrease that particular field's importance in the query. For example, the query below:

```
qf="fieldOne^2.3 fieldTwo fieldThree^0.4"
```

assigns `fieldOne` a boost of 2.3, leaves `fieldTwo` with the default boost (because no boost factor is specified), and `fieldThree` a boost of 0.4. These boost factors make matches in `fieldOne` much more significant than matches in `fieldTwo`, which in turn are much more significant than matches in `fieldThree`.

The mm (Minimum Should Match) Parameter

When processing queries, Lucene/Solr recognizes three types of clauses: mandatory, prohibited, and "optional" (also known as "should" clauses). By default, all words or phrases specified in the `q` parameter are treated as "optional" clauses unless they are preceded by a "+" or a "-". When dealing with these "optional" clauses, the `mm` parameter makes it possible to say that a certain minimum number of those clauses must match. The DisMax query parser offers great flexibility in how the minimum number can be specified.

The table below explains the various ways that `mm` values can be specified.

Syntax	Example	Description
Positive integer	3	Defines the minimum number of clauses that must match, regardless of how many clauses there are in total.
Negative integer	-2	Sets the minimum number of matching clauses to the total number of optional clauses, minus this value.
Percentage	75%	Sets the minimum number of matching clauses to this percentage of the total number of optional clauses. The number computed from the percentage is rounded down and used as the minimum.
Negative percentage	-25%	Indicates that this percent of the total number of optional clauses can be missing. The number computed from the percentage is rounded down, before being subtracted from the total to determine the minimum number.
An expression beginning with a positive integer followed by a > or < sign and another value	3<90%	Defines a conditional expression indicating that if the number of optional clauses is equal to (or less than) the integer, they are all required, but if it's greater than the integer, the specification applies. In this example: if there are 1 to 3 clauses they are all required, but for 4 or more clauses only 90% are required.
Multiple conditional expressions involving > or < signs	2<-25% 9<-3	Defines multiple conditions, each one being valid only for numbers greater than the one before it. In the example at left, if there are 1 or 2 clauses, then both are required. If there are 3-9 clauses all but 25% are required. If there are more than 9 clauses, all but three are required.

When specifying `mm` values, keep in mind the following:

- When dealing with percentages, negative values can be used to get different behavior in edge cases. 75% and -25% mean the same thing when dealing with 4 clauses, but when dealing with 5 clauses 75% means 3 are required, but -25% means 4 are required.
- If the calculations based on the parameter arguments determine that no optional clauses are needed, the usual rules about Boolean queries still apply at search time. (That is, a Boolean query containing no required clauses must still match at least one optional clause).
- No matter what number the calculation arrives at, Solr will never use a value greater than the number of optional clauses, or a value less than 1. (In other words, no matter how low or how high the calculated result, the minimum number of required matches will never be less than 1 or greater than the number of clauses.)

The default value of `mm` is 100% (meaning that all clauses must match).

The `pf` (Phrase Fields) Parameter

Once the list of matching documents has been identified using the `fq` and `qf` parameters, the `pf` parameter can be used to "boost" the score of documents in cases where all of the terms in the `q` parameter appear in close proximity.

The format is the same as that used by the `qf` parameter: a list of fields and "boosts" to associate with each of them when making phrase queries out of the entire `q` parameter.

The `ps` (Phrase Slop) Parameter

The `ps` parameter specifies the amount of "phrase slop" to apply to queries specified with the `pf` parameter. Phrase slop is the number of positions one token needs to be moved in relation to another token in order to match a phrase specified in a query.

The `qs` (Query Phrase Slop) Parameter

The `qs` parameter specifies the amount of slop permitted on phrase queries explicitly included in the user's query string with the `qf` parameter. As explained above, slop refers to the number of positions one token needs to be moved in relation to another token in order to match a phrase specified in a query.

The `tie` (Tie Breaker) Parameter

The `tie` parameter specifies a float value (which should be something much less than 1) to use as tiebreaker in DisMax queries.

When a term from the user's input is tested against multiple fields, more than one field may match. If so, each field will generate a different score based on how common that word is in that field (for each document relative to all other documents). The `tie` parameter lets you control how much the final score of the query will be influenced by the scores of the lower scoring fields compared to the highest scoring field.

A value of "0.0" makes the query a pure "disjunction max query": that is, only the maximum scoring subquery contributes to the final score. A value of "1.0" makes the query a pure "disjunction sum query" where it doesn't matter what the maximum scoring sub query is, because the final score will be the sum of the subquery scores. Typically a low value, such as 0.1, is useful.

The bq (Boost Query) Parameter

The `bq` parameter specifies a raw query string (expressed in Solr query syntax) that will be included with the user's query to influence the score. For example, if you wanted to add a relevancy boost for recent documents:

```
q=cheese bq=date\[NOW/DAY-1YEAR TO NOW/DAY\]
```

You can specify multiple `bq` parameters. If you want your query to be parsed as separate clauses with separate boosts, use multiple `bq` parameters.

The bf (Boost Functions) Parameter

The `bf` parameter specifies functions (with optional boosts) that will be included in the user's query to influence the score. Any function supported natively by Solr can be used, along with a boost value. For example:

```
recip(rord(myfield),1,2,3)^1.5
```

Specifying functions with the `bf` parameter is just shorthand for using the `val : "...function..."` syntax in a `bq` parameter.

For example, if you want to show the most recent documents first, use

```
recip(rord(creationDate),1,1000,1000)
```

Examples of Queries Submitted to the DisMax Query Parser

Normal results for the word "video" using the `StandardRequestHandler` with the default search field:

```
http://localhost:8983/solr/select/?q=video&fl=name+score
```

The "dismax" handler is configured to search across the text, features, name, sku, id, manu, and cat fields all with varying boosts designed to ensure that "better" matches appear first, specifically: documents which match on the name and cat fields get higher scores.

```
http://localhost:8983/solr/select/?defType=dismax&q=video
```

Note that this instance is also configured with a default field list, which can be overridden in the URL.

```
http://localhost:8983/solr/select/?defType=dismax&q=video&fl=*,score
```

You can also override which fields are searched on and how much boost each field gets.

```
http://localhost:8983/solr/select/?defType=dismax&q=video&qf=features
^20.0+text^0.3
```

You can boost results that have a field that matches a specific value.

```
http://localhost:8983/solr/select/?defType=dismax&q=video&bq=cat:electronics ^5.0
```

Another instance of the handler is registered using the `qt` "instock" and has slightly different configuration options, notably: a filter for (you guessed it) `inStock:true`).

```
http://localhost:8983/solr/select/?defType=dismax&q=video&fl=name,score,inStock
```

```
http://localhost:8983/solr/select/?defType=dismax&q=video&qt=instock&fl=name,score,i
```

One of the other really cool features in this handler is robust support for specifying the "BooleanQuery.minimumNumberShouldMatch" you want to be used based on how many terms are in your user's query. These allows flexibility for typos and partial matches. For the `dismax` handler, one and two word queries require that all of the optional clauses match, but for three to five word queries one missing word is allowed.

```
http://localhost:8983/solr/select/?defType=dismax&q=belkin+ipod
```

```
http://localhost:8983/solr/select/?defType=dismax&q=belkin+ipod+gibberish
```

```
http://localhost:8983/solr/select/?defType=dismax&q=belkin+ipod+apple
```

Just like the `StandardRequestHandler`, it supports the `debugQuery` option to viewing the parsed query, and the score explanations for each document.

```
http://localhost:8983/solr/select/?defType=dismax&q=belkin+ipod+gibberish&debugQuery
```

```
http://localhost:8983/solr/select/?defType=dismax&q=video+card&debugQuery=true
```

The Extended DisMax Query Parser

The Extended DisMax (eDisMax) query parser is an improved version of the [DisMax query parser](#). In addition to supporting all the DisMax query parser parameters, Extended DisMax:

- supports the full Lucene query parser syntax
- supports queries such as AND, OR, NOT, -, and "

- treats and/or as AND/OR in Lucene syntax mode
- includes improved smart partial escaping in the case of syntax errors; fielded queries, +/-, and phrase queries are still supported in this mode
- improves proximity boosting by using word shingles; you do not need the query to match all words in the document before proximity boosting is applied
- includes advanced stopwords handling: stopwords are not required in the mandatory part of the query but are still used in the proximity boosting part. If a query consists of all stopwords, such as "to be or not to be", then all words are required
- includes improved boost function: in Extended DisMax, the `boost` function is a multiplier rather than an addend, improving your boost results; the additive boost functions of DisMax (`bf` and `bq`) are also supported
- Supports pure negative nested queries: queries such as `+foo (-foo)` will match all documents

 The Extended DisMax query parser is still under active development, so it may change in the future. However, many organizations are already using it in production with great success.

Extended DisMax Parameters

In addition to all the [DisMax parameters](#), Extended DisMax includes these query parameters:

Parameter	Description
boost	A multivalued list of strings parsed as queries with scores multiplied by the score from the main query for all matching documents.
lowercaseOperators	A Boolean parameter indicating if lowercase "and" and "or" should be treated the same as operators "AND" and "OR".
pf2	A multivalued list of fields with optional weights, based on pairs of word shingles.
pf3	A multivalued list of fields with optional weights, based on triplets of word shingles.
stopwords	A Boolean parameter indicating if the <code>StopFilterFactory</code> configured in the query analyzer should be respected when parsing the query: if it is false, then the <code>StopFilterFactory</code> in the query analyzer is ignored.

The sections below explain these parameters in detail.

The boost Parameter

A multivalued list of strings that will be parsed as queries and whose scores will be multiplied by the score from the main query for all matching documents. This parameter is shorthand for wrapping the query produced by eDisMax using the `BoostQParserPlugin`.

The `lowercaseOperators` Parameter

A Boolean parameter indicating if lowercase "and" and "or" should be treated the same as operators "AND" and "OR".

The `pf2` Parameter

A multivalued list of fields with optional weights. Similar to `pf`, except that instead of building a phrase per field out of all the words in the input, it builds a set of phrases for each field out of each pair of word shingles (or word-based bigrams).

The `pf3` Parameter

A multivalued list of fields with optional weights. Similar to `pf`, except that instead of building a phrase per field out of all the words in the input, it builds a set of phrases for each field out of each triplet of word shingles (or word-based trigrams).

The `stopwords` Parameter

A Boolean parameter indicating if the `StopFilterFactory` configured in the query analyzer should be respected when parsing the query: if it is false, then the `StopFilterFactory` in the query analyzer is ignored.

Examples of Queries Submitted to the Extended DisMax Query Parser

Boost the result of the query term "hello" based on the document's popularity:

<http://localhost:8983/solr/select/?defType=edismax&q=hello&pf=text&qf=text&boost=popularity>

Search for iPods OR video:

<http://localhost:8983/solr/select/?defType=edismax&q=ipod> OR video

Local Parameters in Queries

Local parameters are arguments in a Solr request that are specific to a query parameter. Local parameters provide a way to add meta-data to certain argument types such as query strings. (In Solr documentation, local parameters are sometimes referred to as `LocalParams`.)

Local parameters are specified as prefixes to arguments. Take the following query argument, for example:

```
q=solr rocks
```

We can prefix this query string with local parameters to provide more information to the Standard Query Parser. For example, we can change the default operator type to "AND" and the default field to "title":

```
q={!q.op=AND df=title}solr rocks
```

These local parameters would change the query to require a match on both "solr" and "rocks" while searching the "title" field by default.

Basic Syntax of Local Parameters

To specify a local parameter, insert the following before the argument to be modified:

- Begin with {!
- Insert any number of key=value pairs separated by white space
- End with } and immediately follow with the query argument

You may specify only one local parameters prefix per argument. Values in the key-value pairs may be quoted via single or double quotes, and backslash escaping works within quoted strings.

Query Type Short Form

If a local parameter value appears without a name, it is given the implicit name of "type". This allows short-form representation for the type of query parser to use when parsing a query string. Thus

```
q={!dismax qf=myfield}solr rocks
```

is equivalent to:

```
q={!type=dismax qf=myfield}solr rocks
```

Specifying the Parameter Value with the ' v ' Key

A special key of `v` within local parameters is an alternate way to specify the value of that parameter.

```
q={!dismax qf=myfield}solr rocks
```

is equivalent to

```
q={!type=dismax qf=myfield v='solr rocks'}
```

Parameter Dereferencing

Parameter dereferencing or indirection lets you use the value of another argument rather than specifying it directly. This can be used to simplify queries, decouple user input from query parameters, or decouple front-end GUI parameters from defaults set in `solrconfig.xml`.

```
q={!dismax qf=myfield}solr rocks
```

is equivalent to:

```
q={!type=dismax qf=myfield v=$qq}&qq=solr rocks
```

Function Queries

Function Query parameters enable you to generate a relevancy score using the actual value of one or more numeric fields. Function queries are supported by the [DisMax](#), [Extended DisMax](#), and [standard](#) query parsers.

The table below summarizes the functions available for function queries. For more details on these function queries, see <https://wiki.apache.org/solr/FunctionQuery>.

Function	Description	Syntax Examples
abs	Returns the absolute value of the specified value or function.	abs(x) abs(-5)
constant	Specifies a floating point constant.	1.5 val :1.5
div	Divides one value or function by another. div(x,y) divides x by y.	div(1,y) div(sum(x,100),max(y,1))
dist	Return the distance between two vectors (points) in an n-dimensional space. Takes in the power, plus two or more ValueSource instances and calculates the distances between the two vectors. Each ValueSource must be a number. There must be an even number of ValueSource instances passed in and the method assumes that the first half represent the first vector and the second half represent the second vector.	dist(2, x, y, 0, 0) - calculates the Euclidean distance between (0,0) and (x,y) for each document dist(1, x, y, 0, 0) - calculates the Manhattan (taxicab) distance between (0,0) and (x,y) for each document dist(2, x,y,z,0,0,0) - Euclidean distance between (0,0,0) and (x,y,z) for each document. dist(1,x,y,z,e,f,g) - Euclidean distance between (x,y,z) and (e,f,g) where each letter is a field name
fieldvalue	Returns the numeric field value of an indexed (not multi-valued) field with a maximum of one value per document. The syntax is simply the field name by itself. 0 is returned for documents without a value in the field.	myFloatField val :myFloatField

hsin	The Haversine distance calculates the distance between two points on a sphere when traveling along the sphere. The values must be in radians. <code>hsin</code> also take a Boolean argument to specify whether the function should convert its output to radians.	<code>hsin(2, true, x, y, 0, 0)</code>
linear	Implements $m*x+c$ where m and c are constants and x is an arbitrary function. This is equivalent to <code>sum(product(m,x),c)</code> , but slightly more efficient as it is implemented as a single function.	<code>linear(x,m,c)</code> <code>linear(x,2,4)</code> returns $2*x+4$
log	Returns the log base 10 of the specified function.	<code>log(x)log(sum(x,100))</code>
map	Maps any values of the function x that fall within min and max inclusive to the specified target. The arguments $min,max,target$ are constants. The function outputs the field's value if it does not fall between min and max .	<code>map(x,min,max,target)</code> <code>map(x,0,0,1)</code> - changes any values of 0 to 1. This can be useful in handling default 0 values. <code>map(x,min,max,target,altarg)</code> <code>map(x,0,0,1,0)</code> - changes any values of 0 to 1 and if the value is not zero it can be set to the value of the 5th argument instead of defaulting to the field's value.
max	Returns the max of another function and a constant, which are specified as arguments: <code>max(x,c)</code> The <code>max</code> function is useful for "bottoming out" another function at some constant.	<code>max(myfield,0)</code>

ms	<p>Returns milliseconds of difference between its arguments. Dates are relative to the Unix or POSIX time epoch, midnight, January 1, 1970 UTC.</p> <p>Arguments may be numerically indexed date fields such as <code>TrieDate</code> (the default in 1.4), or date math based on a constant date or <code>NOW</code>.</p>	<p><code>ms ()</code> Equivalent to <code>ms(NOW)</code>, number of milliseconds since the epoch.</p> <p><code>ms (a)</code> Returns the number of milliseconds since the epoch that the argument represents. Examples: <code>ms(NOW/DAY)</code> <code>ms(2000-01-01T00:00:00Z)</code> <code>ms(mydatefield)</code></p> <p><code>ms (a , b)</code> Returns the number of milliseconds that <code>b</code> occurs before <code>a</code> (that is, <code>a - b</code>). Note that this offers higher precision than <code>sub(a,b)</code> because the arguments are not converted to floating point numbers before subtraction. Examples: <code>ms(NOW,mydatefield)</code> <code>ms(mydatefield,2000-01-01T00:00:00Z)</code> <code>ms(datefield1,datefield2)</code></p>
----	--	--

ord	<p>Returns the ordinal of the indexed field value within the indexed list of terms for that field in Lucene index order (lexicographically ordered by unicode value), starting at 1. In other words, for a given field, all values are ordered lexicographically; this function then returns the offset of a particular value in that ordering. The field must have a maximum of one value per document (not multi-valued). 0 is returned for documents without a value in the field.</p> <div data-bbox="305 835 776 1087" style="border: 1px solid #ccc; background-color: #ffffcc; padding: 5px;"> <p> <code>ord()</code> depends on the position in an index and can thus change when other documents are inserted or deleted.</p> </div> <p>See also <code>rord</code> below.</p>	<pre>ord(myIndexedField) val_ : "ord(myIndexedField) "</pre> <p>Example: If there were only three values ("apple","banana","pear") for a particular field, then:</p> <pre>ord("apple")=1ord("banana")=2ord("pear")=3</pre>
pow	<p>Raises the specified base to the specified power. <code>pow(x,y)</code> raises <code>x</code> to the power of <code>y</code>.</p>	<pre>pow(x,y)pow(x,log(y)) pow(x,0.5) is the same as sqrt</pre>
product	<p>Returns the product of multiple values or functions, which are specified in a comma-separated list.</p>	<pre>product(x,y,...) product(x,2) product(x,y)</pre>

query	<p>Returns the score for the given subquery, or the default value for documents not matching the query.</p> <p>Any type of subquery is supported through either parameter dereferencing <code>\$otherparam</code> or direct specification of the query string in the Local Parameters through the <code>v</code> key.</p>	<pre>query(subquery, default) q=product(popularity, query({!dismax v='solr rocks'})) returns the product of the popularity and the score of the DisMax query. q=product(popularity, query(\$qq))&qq={!dismax}solr rocks is equivalent to the previous query, using parameter dereferencing. q=product(popularity, query(\$qq,0.1))&qq={!dismax}solr rocks specifies a default score of 0.1 for documents that don't match the DisMax query.</pre>
recip	<p>Performs a reciprocal function with <code>recip(myfield,m,a,b)</code> implementing $a/(m*x+b)$. <code>m,a,b</code> are constants, and <code>x</code> is any arbitrarily complex function. When <code>a</code> and <code>b</code> are equal, and $x \geq 0$, this function has a maximum value of 1 that drops as <code>x</code> increases. Increasing the value of <code>a</code> and <code>b</code> together results in a movement of the entire function to a flatter part of the curve. These properties can make this an ideal function for boosting more recent documents when <code>x</code> is <code>rord(datefield)</code>.</p>	<pre>recip(myfield,m,a,b) recip(rord(creationDate),1,1000,1000)</pre>
rord	<p>Returns the reverse ordering of that returned by <code>ord</code>.</p>	<pre>rord(myDateField) val_:"rord(myDateField)" Example: rord(myDateField) is a metric for how old a document is. The youngest document will return 1. The oldest document will return the total number of documents.</pre>

scale	<p>Scales values of the function <code>x</code> such that they fall between the specified <code>minTarget</code> and <code>maxTarget</code> inclusive.</p> <p>The current implementation traverses all of the function values to obtain the min and max, so it can pick the correct scale.</p> <p>The current implementation cannot distinguish when documents have been deleted or documents that have no value. It uses 0.0 values for these cases. This means that if values are normally all greater than 0.0, one can still end up with 0.0 as the min value to map from. In these cases, an appropriate <code>map()</code> function could be used as a workaround to change 0.0 to a value in the real range, as shown here:</p> <pre>scale(map(x,0,0,5),1,2)</pre>	<pre>scale(x,minTarget,maxTarget)</pre> <p><code>scale(x,1,2)</code> scales the values of <code>x</code> such that all values will be between 1 and 2 inclusive.</p>
sqedist	<p>The Square Euclidean distance calculates the 2-norm (Euclidean distance) but does not take the square root, thus saving a fairly expensive operation. It is often the case that applications that care about Euclidean distance do not need the actual distance, but instead can use the square of the distance. There must be an even number of <code>ValueSource</code> instances passed in and the method assumes that the first half represent the first vector and the second half represent the second vector.</p>	<pre>sqedist(x_td, y_td, 0, 0)</pre>
sqrt	<p>Returns the square root of the specified value or function.</p>	<pre>sqrt(x) sqrt(100) sqrt(sum(x,100))</pre>

strdist	<p>Calculate the distance between two strings. Uses the Lucene spell checker <code>StringDistance</code> interface and supports all of the implementations available in that package, plus allows applications to plug in their own via Solr's resource loading capabilities. <code>strdist</code> takes (string1, string2, distance measure). Possible values for distance measure are:</p> <p>jw: Jaro-Winkler</p> <p>edit: Levenstein or Edit distance</p> <p>ngram: The <code>NGramDistance</code>, if specified, can optionally pass in the ngram size too. Default is 2.</p> <p>FQN: Fully Qualified class Name for an implementation of the <code>StringDistance</code> interface. Must have a no-arg constructor.</p>	<pre>strdist("SOLR",id,edit)</pre>
sub	Returns x-y from <code>sub(x,y)</code> .	<pre>sub(myfield,myfield2) sub(100,sqrt(myfield))</pre>
sum	Returns the sum of multiple values or functions, which are specified in a comma-separated list.	<pre>sum(x,y,...) sum(x,1) sum(x,y) sum(sqrt(x),log(y),z,0.5)</pre>

top	<p>Causes the function query argument to derive its values from the top-level IndexReader containing all parts of an index. For example, the ordinal of a value in a single segment will be different from the ordinal of that same value in the complete index. The <code>ord()</code> and <code>rord()</code> functions implicitly use <code>top()</code>, and hence <code>ord(foo)</code> is equivalent to <code>top(ord(foo))</code>.</p>	
-----	---	--

Using FunctionQuery

There are two principal ways of including function queries in a Solr query:

- Introduce a function query with the `val` keyword. For example:

```
val :mynumericfield val : "recip(rord(myfield),1,2,3)"
```

- Use a parameter that has an explicit type of FunctionQuery, such as the DisMax query parser's [bf \(boost function\) parameter](#). Note that the `bf` parameter actually takes a list of function queries separated by white space and each with an optional boost. Make sure you eliminate any internal white space in single function queries when using `bf`. For example:

```
q=dismax&bf="ord(popularity)^0.5 recip(rord(price),1,1000,1000)^0.3"
```

Functions must be expressed as function calls (for example, `sum(a,b)` instead of simply `a+b`).

Example of Function Queries Using the top Function

To give you a better understanding of how function queries can be used in Solr, suppose an index stores the dimensions in meters `x,y,z` of some hypothetical boxes with arbitrary names stored in field `boxname`. Suppose we want to search for box matching name `findbox` but ranked according to volumes of boxes. The query parameters would be:

```
q=boxname:findbox val : "product(product(x,y),z)"
```

- This query will rank the results based on volumes. In order to get the computed volume, you will need to add the parameter:

```
&fl=*, score
```

where score will contain the resultant volume.

- Suppose that you also have a field storing the weight of the box as 'weight'. To sort by the density of the box and return the value of the density in score, you would submit the following query:

```
http://localhost:8983/solr/select/?q=boxname:findbox val
:"div(weight,product(product(x,y),z))"&fl=boxname x y z weight score
```

Sort By Function

You can sort your query results by the output of a function. For example, to sort results by distance, you could enter:

```
http://localhost:8983/solr/select?q=*:*&sort=dist(2 , point1, point2) desc
```

Sort By Function also supports pseudo-fields: fields can be generated dynamically and return results as though it was normal field in the index. For example, `&fl=id,sum(x, y),score` would return:

```
<str name="id">foo</str>
<float name="sum(x,y)">40</float>
<float name="score">0.343</float>
```

Highlighting

Solr provides a collection of highlighting utilities which can be called by various Request Handlers to include "highlighted" matches in field values. These highlighting utilities may be used with either the [DisMax](#), [Extended DisMax](#), or [standard](#) query parser.

 Only text that has been both indexed and stored may be highlighted.

Some parameters may be overridden on a per-field basis with the following syntax:

`f.<fieldName>.<originalParam>=<value>`. For example: `f.contents.hl.snippets=2`

The table below describes Solr's parameters for highlighting.

Parameter	Description
hl	<p>When set to "true", enables highlighted snippets to be generated in the query response. If set to "false" or to a blank or missing value, disables highlighting.</p> <p>The default value is blank, which disables highlighting.</p>
hl.fl	<p>Specifies a list of fields to highlight. Accepts a comma- or space-delimited list of fields for which Solr should generate highlighted snippets. If left blank, highlights the defaultSearchField (or the field specified the <code>df</code> parameter if used) for the StandardRequestHandler. For the DisMaxRequestHandler, the <code>qf</code> fields are used as defaults.</p> <p>A '*' can be used to match field globs, such as 'text_*' or even '*' to highlight on all fields where highlighting is possible. When using '*', consider adding <code>hl.requireFieldMatch=true</code>.</p> <p>The default value is blank.</p>
hl.snippets	<p>Specifies maximum number of highlighted snippets to generate per field. Note: it is possible for any number of snippets from zero to this value to be generated. This parameter accepts per-field overrides.</p> <p>The default value is "1".</p>

hl.fragsize	<p>Specifies the size, in characters, of fragments to consider for highlighting. "0" indicates that the whole field value should be used (no fragmenting). This parameter accepts per-field overrides.</p> <p>The default value is "100".</p>
hl.mergeContinuous	<p>Instructs Solr to collapse contiguous fragments into a single fragment. "true" indicates contiguous fragments will be collapsed into single fragment. This parameter accepts per-field overrides.</p> <p>The default value is "false", which is also the backward-compatible setting.</p>
hl.requireFieldMatch	<p>If set to true, highlights terms only if they appear in the specified field. Normally, terms are highlighted in all requested fields regardless of which field matched the query.</p> <p>The default value is "false".</p>
hl.maxAnalyzedChars	<p>Specifies the number of characters into a document that Solr should look for suitable snippets.</p> <p>The default value is "51200".</p>
hl.alternateField	<p>Specifies a field to be used as a backup default summary if Solr cannot generate a snippet (because no terms match). This parameter accepts per-field overrides.</p> <p>By default, Solr does not select a field for a backup summary.</p>
hl.maxAlternateFieldLength	<p>Specifies the maximum number of characters of the field to return. Any value less than or equal to 0 means the field's length is unlimited.</p> <p>The default value is unlimited.</p> <p>Requires the use of the <code>hl.alternateField</code> parameter.</p>
hl.formatter	<p>Selects a formatter for the highlighted output. Currently the only legal value is "simple", which surrounds a highlighted term with a customizable pre- and post-text snippet. This parameter accepts per-field overrides.</p> <p>The default value is "simple".</p>

hl.simple.pre hl.simple.post	<p>Specifies the text that should appear before and after a highlighted term when using the simple formatter. This parameter accepts per-field overrides.</p> <p>The default values are "" and "".</p>
hl.fragmenter	<p>Specifies a text snippet generator for highlighted text. The standard fragmenter is <code>gap</code> (which is so called because it creates fixed-sized fragments with gaps for multi-valued fields). Another option is <code>regex</code>, which tries to create fragments that resemble a specified regular expression.</p> <p>The <code>hl.fragmenter</code> parameter accepts per-field overrides.</p> <p>The default value is <code>gap</code>.</p>
hl.useFastVectorHighlighter	<p>The <code>FastVectorHighlighter</code> is a <code>TermVector</code>-based highlighter that offers higher performance than the standard highlighter in many cases. To use the <code>FastVectorHighlighter</code>, set this parameter to <code>true</code>. You must also turn on <code>termVectors</code>, <code>termPositions</code>, and <code>termOffsets</code>.</p>
hl.phraseLimit	<p>To improve the performance of the <code>FastVectorHighlighter</code>, you can set a limit on the number (int) of phrases to be analyzed for highlighting. The default value for this parameter is <code>integer.MAX_VALUE</code>.</p>
hl.usePhraseHighlighter	<p>If set to "true," instructs Solr to use the <code>Lucene SpanScorer</code> class to highlight phrase terms only when they appear within the query phrase in the document. The default is "true."</p>
hl.highlightMultiTerm	<p>If set to "true," instructs Solr to highlight phrase terms that appear in multi-term queries. The default is "true."</p>
hl.regex.slop	<p>Specifies the factor by which the <code>regex</code> fragmenter can stray from the ideal fragment size (given by <code>hl.fragsize</code>) to accommodate a regular expression. For instance, a <code>slop</code> of 0.2 with <code>fragsize</code> of 100 should yield fragments between 80 and 120 characters in length. It is usually good to provide a slightly smaller <code>fragsize</code> when using the <code>regex</code> fragmenter.</p> <p>The default value is 0.6.</p>

hl.regex.pattern	Specifies the regular expression for fragmenting. This could be used to extract sentences.
hl.regex.maxAnalyzedChars	<p>Instructs Solr to analyze only this many characters from a field when using the <code>regex</code> fragmenter (after which, the fragmenter produces fixed-sized fragments). Applying a complicated <code>regex</code> to a huge field is computationally expensive.</p> <p>The default value is "10000".</p>

MoreLikeThis

The `MoreLikeThis` component enables users to query for results similar to the specified terms.

`MoreLikeThis` constructs a Lucene query based on terms in a document. For best results, use stored term vectors in the `schema.xml` for fields specified for similarity. For example:

```
<field name="cat" ... termVectors="true" />
```

If term vectors are not stored, `MoreLikeThis` will generate terms from stored fields.

Common Parameters for MoreLikeThis

The table below summarizes the `MoreLikeThis` parameters supported by Lucene/Solr.

Parameter	Description
<code>mlt.fl</code>	Specifies the fields to use for similarity. If possible, these should have a stored <code>TermVector</code> .
<code>mlt.mintf</code>	Specifies the Minimum Term Frequency—the frequency below which terms will be ignored in the source doc.
<code>mlt.mindf</code>	Specifies the Minimum Document Frequency—the frequency at which words will be ignored which do not occur in at least this many docs.
<code>mlt.minwl</code>	Sets the minimum word length below which words will be ignored.
<code>mlt.maxwl</code>	Sets the maximum word length above which words will be ignored.
<code>mlt.maxqt</code>	Sets the maximum number of query terms that will be included in any generated query.
<code>mlt.maxntp</code>	Sets the maximum number of tokens to parse in each example document field that is not stored with <code>TermVector</code> support.
<code>mlt.boost</code>	[true/false] set if the query will be boosted by the interesting term relevance.
<code>mlt.qf</code>	Query fields and their boosts using the same format as that used by the <code>DisMaxRequestHandler</code> . These fields must also be specified in <code>mlt.fl</code> .

Parameters for the StandardRequestHandler

This method returns similar documents for each document in the response set.

Parameter	Description
mlt	If set to true, activates the <code>MoreLikeThis</code> component and enables Solr to return <code>MoreLikeThis</code> results.
mlt.count	Specifies the number of similar documents to be returned for each result. The default value is 5.

Parameters for the `MoreLikeThis` Request Handler

The table below summarizes parameters accessible through the `MoreLikeThisHandler`. It supports faceting, paging, and filtering using common query parameters.

Parameter	Description
mlt.match.include	Specifies whether or not the response should include the matched document. If set to false, the response will look like a normal select response.
mlt.match.offset	Specifies an offset into the main query search results to locate the document on which the <code>MoreLikeThis</code> query should operate. By default, the query operates on the first result for the <code>q</code> parameter.
mlt.interestingTerms	Controls how the <code>MoreLikeThis</code> component presents the "interesting" terms (the top TF/IDF terms) for the query. Supports three settings. The setting <code>list</code> lists the terms. The setting <code>none</code> lists no terms. The setting <code>details</code> lists the terms along with the boost value used for each term. Unless <code>mlt.boost=true</code> , all terms will have <code>boost=1.0</code> .

Faceting

As described in [Overview of Searching in Solr](#), faceting is the arrangement of search results into categories based on indexed terms. Searchers are presented with the indexed terms, along with numerical counts of how many matching documents were found were each term. Faceting makes it easy for users to explore search results, narrowing in on exactly the results they are looking for.

Topics covered on this page:

- [General Parameters](#)
- [Field-Value Faceting Parameters](#)
- [Range Faceting](#)
- [Date Faceting Parameters](#)
- [LocalParams for Faceting](#)

General Parameters

The table below summarizes the general parameters for controlling faceting.

Parameter	Description
facet	If set to true, enables faceting.
facet.query	Specifies a Lucene query to generate a facet count.

These parameters are described in the sections below.

The `facet` Parameter

If set to "true," this parameter enables facet counts in the query response. If set to "false" to a blank or missing value, this parameter disables faceting. None of the other parameters listed below will have any effect unless this parameter is set to "true." The default value is blank.

The `facet.query` Parameter

This parameter allows you to specify an arbitrary query in the Lucene default syntax to generate a facet count. By default, Solr's faceting feature automatically determines the unique terms for a field and returns a count for each of those terms. Using `facet.query`, you can override this default behavior and select exactly which terms or expressions you would like to see counted. In a typical implementation of faceting, you will specify a number of `facet.query` parameters. This parameter can be particularly useful for numeric-range-based facets or prefix-based facets.

You can set the `facet.query` parameter multiple times to indicate that multiple queries should be used as separate facet constraints.

To use facet queries in a syntax other than the default syntax, prefix the facet query with the name of the query notation. For example, to use the hypothetical `myfunc` query parser, you could set the `facet.query` parameter like so:

```
facet.query={!myfunc}name~fred
```

Field-Value Faceting Parameters

Several parameters can be used to trigger faceting based on the indexed terms in a field.

When using this parameter, it is important to remember that "term" is a very specific concept in Lucene: it relates to the literal field/value pairs that are indexed after any analysis occurs. For text fields that include stemming, lowercasing, or word splitting, the resulting terms may not be what you expect. If you want Solr to perform both analysis (for searching) and faceting on the full literal strings, use the `copyField` directive in the `schema.xml` file to create two versions of the field: one Text and one String. Make sure both are `indexed="true"`. (For more information about the `copyField` directive, see [Documents, Fields, and Schema Design](#).)

The table below summarizes Solr's field value faceting parameters.

Parameter	Description
facet.field	Identifies a field to be treated as a facet.
facet.prefix	Limits the terms used for faceting to those that begin with the specified prefix.
facet.sort	Controls how faceted results are sorted.
facet.limit	Controls how many constraints should be returned for each facet.
facet.offset	Specifies an offset into the facet results at which to begin displaying facets.
facet.mincount	Specifies the minimum counts required for a facet field to be included in the response.
facet.missing	Controls whether Solr should compute a count of all matching results which have no value for the field, in addition to the Term-based constraints of a facet field.
facet.method	Selects the algorithm or method Solr should use when faceting a field.

<code>facet.enum.cache.minDF</code>	Specifies the minimum document frequency (the number of documents matching a term) for which the <code>filterCache</code> should be used when determining the constraint count for that term.
-------------------------------------	---

These parameters are described in the sections below.

The `facet.field` Parameter

The `facet.field` parameter identifies a field that should be treated as a facet. It iterates over each Term in the field and generate a facet count using that Term as the constraint. This parameter can be specified multiple times in a query to select multiple facet fields.

 If you do not set this parameter to at least one field in the schema, none of the other parameters described in this section will have any effect.

The `facet.prefix` Parameter

The `facet.prefix` parameter limits the terms on which to facet to those starting with the given string prefix. This does not limit the query in any way, only the facets that would be returned in response to the query.

This parameter can be specified on a per-field basis with the syntax of `f.<fieldname>.facet.prefix`.

The `facet.sort` Parameter

This parameter determines the ordering of the facet field constraints.

 The true/false values for this parameter were deprecated in Solr 1.4.

<code>facet.sort</code> Setting	Results
<code>count</code>	Sort the constraints by count (highest count first).
<code>index</code>	Return the constraints sorted in their index order (lexicographic by indexed term). For terms in the ASCII range, this will be alphabetically sorted.

The default is `count` if `facet.limit` is greater than 0, otherwise, the default is `index`.

This parameter can be specified on a per-field basis with the syntax of `f.<fieldname>.facet.sort`.

The `facet.limit` Parameter

This parameter specifies the maximum number of constraint counts (essentially, the number of facets for a field that are returned) that should be returned for the facet fields. A negative value means that Solr will return unlimited number of constraint counts.

The default value is 100.

This parameter can be specified on a per-field basis to apply a distinct limit to each field with the syntax of `f.<fieldname>.facet.limit`.

The `facet.offset` Parameter

The `facet.offset` parameter indicates an offset into the list of constraints to allow paging.

The default value is 0.

This parameter can be specified on a per-field basis with the syntax of `f.<fieldname>.facet.offset`.

The `facet.mincount` Parameter

The `facet.mincount` parameter specifies the minimum counts required for a facet field to be included in the response. If a field's counts are below the minimum, the field's facet is not returned.

The default value is 0.

This parameter can be specified on a per-field basis with the syntax of `f.<fieldname>.facet.mincount`.

The `facet.missing` Parameter

If set to true, this parameter indicates that, in addition to the Term-based constraints of a facet field, a count of all results that match the query but which have no facet value for the field should be computed and returned in the response.

The default value is false.

This parameter can be specified on a per-field basis with the syntax of `f.<fieldname>.facet.missing`.

The `facet.method` Parameter

The `facet.method` parameter selects the type of algorithm or method Solr should use when faceting a field.

Setting	Results
enum	Enumerates all terms in a field, calculating the set intersection of documents that match the term with documents that match the query. This method is recommended for faceting multi-valued fields that have only a few distinct values. The average number of values per document does not matter. For example, faceting on a field with U.S. States such as <code>Alabama</code> , <code>Alaska</code> , ... <code>Wyoming</code> would lead to fifty cached filters which would be used over and over again. The <code>filterCache</code> should be large enough to hold all the cached filters.
fc	Calculates facet counts by iterating over documents that match the query and summing the terms that appear in each document. This is currently implemented using an <code>UnInvertedField</code> cache if the field either is multi-valued or is tokenized (according to <code>FieldType.isTokenized()</code>). Each document is looked up in the cache to see what terms/values it contains, and a tally is incremented for each value. This method is excellent for situations where the number of indexed values for the field is high, but the number of values per document is low. For multi-valued fields, a hybrid approach is used that uses term filters from the <code>filterCache</code> for terms that match many documents. The letters <code>fc</code> stand for field cache.

The default value is `fc` (except for fields using the `BoolField` field type) since it tends to use less memory and is faster when a field has many unique terms in the index.

This parameter can be specified on a per-field basis with the syntax of `f.<fieldname>.facet.method`.

The `facet.enum.cache.minDf` Parameter

This parameter indicates the minimum document frequency (the number of documents matching a term) for which the `filterCache` should be used when determining the constraint count for that term. This is only used with the `facet.method=enum` method of faceting.

A value greater than zero decreases the `filterCache`'s memory usage, but increases the time required for the query to be processed. If you are faceting on a field with a very large number of terms, and you wish to decrease memory usage, try setting this parameter to a value between 25 and 50, and run a few tests. Then, optimize the parameter setting as necessary.

The default value is 0, causing the `filterCache` to be used for all terms in the field.

This parameter can be specified on a per-field basis with the syntax of `f.<fieldname>.facet.enum.cache.minDF`.

Range Faceting

You can use Range Faceting on any date field or any numeric field that supports range queries. This is particularly useful for stitching together a series of range queries (as facet by query) for things like prices. As of Solr 3.1, Range Faceting is preferred over [Date Faceting](#) (described below).

Parameter	Description
facet.range	Specifies the field to facet by range.
facet.range.start	Specifies the start of the facet range.
facet.range.end	Specifies the end of the facet range.
facet.range.gap	Specifies the span of the range as a value to be added to the lower bound.
facet.range.hardend	A boolean parameter that specifies how Solr handles a range gap that cannot be evenly divided between the range start and end values. If true, the last range constraint will have the <code>facet.range.end</code> value as an upper bound. If false, the last range will have the smallest possible upper bound greater than <code>facet.range.end</code> such that the range is the exact width of the specified range gap. The default value for this parameter is false.
facet.range.include	Specifies inclusion and exclusion preferences for the upper and lower bounds of the range. See the <code>facet.range.include</code> topic for more detailed information.
facet.range.other	Specifies counts for Solr to compute in addition to the counts for each facet range constraint.

The `facet.range` Parameter

The `facet.range` parameter defines the field for which Solr should create range facets. For example:

```
facet.range=price&facet.range=age
```

The `facet.range.start` Parameter

The `facet.range.start` parameter specifies the lower bound of the ranges. You can specify this parameter on a per field basis with the syntax of `f.<fieldname>.facet.range.start`. For example:

```
f.price.facet.range.start=0.0&f.age.facet.range.start=10
```

The `facet.range.end` Parameter

The `facet.range.end` specifies the upper bound of the ranges. You can specify this parameter on a per field basis with the syntax of `f.<fieldname>.facet.range.end`. For example:

```
f.price.facet.range.end=1000.0&f.age.facet.range.start=99
```

The facet.range.gap Parameter

The span of each range expressed as a value to be added to the lower bound. For date fields, this should be expressed using the [DateMathParser](#) syntax (such as `facet.range.gap=%2B1DAY ... '+1DAY'`). You can specify this parameter on a per field basis with the syntax of `f.<fieldname>.facet.range.gap`. For example:

```
f.price.facet.range.gap=100&f.age.facet.range.gap=10
```

`facet.date.gap=1,2,3,10` creates 4+ buckets of size, 1, 2, 3 and then 0 or more buckets of 10 days each, depending on the start and end values.

The facet.range.hardend Parameter

The `facet.range.hardend` parameter is a Boolean parameter that specifies how Solr should handle cases where the `facet.range.gap` does not divide evenly between `facet.range.start` and `facet.range.end`. If **true**, the last range constraint will have the `facet.range.end` value as an upper bound. If **false**, the last range will have the smallest possible upper bound greater than `facet.range.end` such that the range is the exact width of the specified range gap. The default value for this parameter is false. This parameter can be specified on a per field basis with the syntax `f.<fieldname>.facet.range.hardend`.

The facet.range.include Parameter

By default, the ranges used to compute range faceting between `facet.range.start` and `facet.range.end` are inclusive of their lower bounds and exclusive of the upper bounds. The "before" range defined with the `facet.range.other` parameter is exclusive and the "after" range is inclusive. This default, equivalent to "lower" below, will not result in double counting at the boundaries. You can use the `facet.range.include` parameter to modify this behavior using the following options:

Option	Description
lower	All gap-based ranges include their lower bound.
upper	All gap-based ranges include their upper bound.
edge	The first and last gap ranges include their edge bounds (lower for the first one, upper for the last one) even if the corresponding upper/lower option is not specified.
outer	The "before" and "after" ranges will be inclusive of their bounds, even if the first or last ranges already include those boundaries.
all	Includes all options: lower, upper, edge, outer.

You can specify this parameter on a per field basis with the syntax of `f.<fieldname>.facet.range.include`, and you can specify it multiple times to indicate multiple choices.

i To ensure you avoid double-counting, do not choose both `lower` and `upper`, do not choose `outer`, and do not choose `all`.

The `facet.range.other` Parameter

The `facet.range.other` parameter specifies that in addition to the counts for each range constraint between `facet.range.start` and `facet.range.end`, counts should also be computed for these options:

Option	Description
<code>before</code>	All records with field values lower than lower bound of the first range.
<code>after</code>	All records with field values greater than the upper bound of the last range.
<code>between</code>	All records with field values between the start and end bounds of all ranges.
<code>none</code>	Do not compute any counts.
<code>all</code>	Compute counts for <code>before</code> , <code>between</code> , and <code>after</code> .

This parameter can be specified on a per field basis with the syntax of `f.<fieldname>.facet.range.other`. In addition to the `all` option, this parameter can be specified multiple times to indicate multiple choices, but `none` will override all other options.

Date Faceting Parameters

As of Solr 3.1, date faceting has been deprecated in favor of [Range Faceting](#), which provides more flexibility with dates and numeric fields. Date Faceting can be used, but are not covered in this guide. For more information on those parameters, which are equivalent to the parameters for [Range Faceting](#), see [Date Faceting Parameters](#) on the Solr Wiki.

LocalParams for Faceting

The LocalParams syntax provides a method of adding metadata to other parameter values, much like XML attributes.

Tagging and Excluding Filters

You can tag specific filters and exclude those filters when faceting. This is useful when doing multi-select faceting.

Consider the following example query with faceting:

```
q=mainquery&fq=status:public&fq=doctype:pdf&facet=on&facet.field=doctype
```

Because everything is already constrained by the filter `doctype:pdf`, the `facet.field=doctype` facet command is currently redundant and will return 0 counts for everything except `doctype:pdf`.

To implement a multi-select facet for `doctype`, a GUI may want to still display the other `doctype` values and their associated counts, as if the `doctype:pdf` constraint had not yet been applied. For example:

```
=== Document Type ===  
[ ] Word (42)  
[x] PDF (96)  
[ ] Excel(11)  
[ ] HTML (63)
```

To return counts for `doctype` values that are currently not selected, tag filters that directly constrain `doctype`, and exclude those filters when faceting on `doctype`.

```
q=mainquery&fq=status:public&fq={!tag=dt}doctype:pdf&facet=on&facet.field={!ex=dt}do
```

Filter exclusion is supported for all types of facets. Both the `tag` and `ex` local parameters may specify multiple values by separating them with commas.

Changing the Output Key

To change the output key for a faceting command, specify a new name with the `key` local parameter. For example:

```
facet.field={!ex=dt key=mylabel}doctype
```

The parameter setting above causes the results to be returned under the key "mylabel" rather than "doctype" in the response. This can be helpful when faceting on the same field multiple times with different exclusions.

Result Grouping

Result Grouping groups documents with a common field value into groups and returns the top documents for each group. For example, if you searched for "DVD" on an electronic retailer's e-commerce site, you might be returned three categories such as "TV and Video," "Movies," and "Computers," with three results per category. In this case, the query term "DVD" appeared in all three categories, so Solr groups them together in order to increase relevancy for the user.

Result Grouping is not to be confused with [Faceting](#). Though it is conceptually similar, faceting returns all relevant results and allows the user to refine the results based on the facet category. For example, if you searched for "shoes" on a footwear retailer's e-commerce site, you would be returned all results for that query term, along with selectable facets such as "size," "color," "brand," and so on.

Request Parameters

Result Grouping takes the following request parameters. Any number of these request parameters can be included in a single request:

Parameter	Type	Description
group	Boolean	If true, query results will be grouped.
group.field	string	The name of the field by which to group results. The field be single-valued, and either be indexed or a field type that has a value source and works in a function query, such as <code>ExternalFileField</code> . It must also be a string-based field, such as <code>StrField</code> or <code>TextField</code>
group.query	query	Return a single group of documents that match the given query.
rows	integer	The number of groups to return. The default value is 10.
start	integer	Specifies an initial offset for the list of groups.
group.limit	integer	Specifies the number of results to return for each group. The default value is 1.
group.offset	integer	Specifies an initial offset for the document list of each group.

sort	sortspec	Specifies how Solr sorts the groups relative to each other. For example, <code>sort=popularity desc</code> will cause the groups to be sorted according to the highest popularity document in each group. The default value is <code>score desc</code> .
group.sort	sortspec	Specifies how Solr sorts documents within a single group. The default value is <code>score desc</code> .
group.format	grouped/simple	If this parameter is set to <code>simple</code> , the grouped documents are presented in a single flat list, and the <code>start</code> and <code>rows</code> parameters affect the numbers of documents instead of groups.
group.main	Boolean	If true, the result of the first field grouping command is used as the main result list in the response, using <code>group.format=simple</code> .
group.ngroups	Boolean	If true, Solr includes the number of groups that have matched the query in the results. The default value is false.
group.truncate	Boolean	If true, facet counts are based on the most relevant document of each group matching the query. The default value is false.
group.cache.percent	integer between 0 and 100	Setting this parameter to a number greater than 0 enables caching for result grouping. Result Grouping executes two searches; this option caches the second search. The default value is 0. Testing has shown that group caching only improves search time with Boolean, wildcard, and fuzzy queries. For simple queries like term or "match all" queries, group caching degrades performance.

Examples

All of the following examples work with the data provided in the Solr Example directory.

Grouping Results by Field

In this example, we will group results based on the `manu_exact` field, which specifies the manufacturer of the items in the sample dataset.

`http://localhost:8983/solr/select?wt=json&indent=true&fl=id,name&q=solr+memory&group`

```
{
```

```

"responseHeader":{
  "status":0,
  "QTime":56,
  "params":{
    "fl":"id,name",
    "indent":"true",
    "q":"solr memory",
    "group.field":"manu_exact",
    "group":"true",
    "wt":"json"}},
"grouped":{
  "manu_exact":{
    "matches":6,
    "groups":[{
      "groupValue":"Apache Software Foundation",
      "doclist":{"numFound":1,"start":0,"docs":[
        {
          "id":"SOLR1000",
          "name":"Solr, the Enterprise Search Server"}]}
    }},
    {
      "groupValue":"Corsair Microsystems Inc.",
      "doclist":{"numFound":2,"start":0,"docs":[
        {
          "id":"VS1GB400C3",
          "name":"CORSAIR ValueSelect 1GB 184-Pin DDR SDRAM Unbuffered DDR 400 (PC
3200) System Memory - Retail"}]}
    }},
    {
      "groupValue":"A-DATA Technology Inc.",
      "doclist":{"numFound":1,"start":0,"docs":[
        {
          "id":"VDBDB1A16",
          "name":"A-DATA V-Series 1GB 184-Pin DDR SDRAM Unbuffered DDR 400 (PC
3200) System Memory - OEM"}]}
    }},
    {
      "groupValue":"Canon Inc.",
      "doclist":{"numFound":1,"start":0,"docs":[
        {
          "id":"0579B002",
          "name":"Canon PIXMA MP500 All-In-One Photo Printer"}]}
    }},
    {
      "groupValue":"ASUS Computer Inc.",
      "doclist":{"numFound":1,"start":0,"docs":[
        {

```

```
        "id": "EN7800GTX/2DHTV/256M",
        "name": "ASUS Extreme N7800GTX/2DHTV (256 MB)"}]
    }
  ]
}
}
```

The response indicates that there are six total matches for our query. For each unique value of `group.field`, Solr returns a `docList` with the top scoring document. The `docList` also includes the total number of matches in that group as the `numFound` value. The groups are sorted by the score of the top document within each group.

We can run the same query with the request parameter `group.main=true`. This will format the results as a single flat document list. This flat format does not include as much information as the normal result grouping query results, but it may be easier for existing Solr clients to parse.

<http://localhost:8983/solr/select?wt=json&indent=true&fl=id,name,manufacturer&q=solr>

```

{
  "responseHeader":{
    "status":0,
    "QTime":1,
    "params":{
      "fl":"id,name,manufacturer",
      "indent":"true",
      "q":"solr memory",
      "group.field":"manu_exact",
      "group.main":"true",
      "group":"true",
      "wt":"json"}},
  "grouped":{},
  "response":{"numFound":6,"start":0,"docs":[
    {
      "id":"SOLR1000",
      "name":"Solr, the Enterprise Search Server"},
    {
      "id":"VS1GB400C3",
      "name":"CORSAIR ValueSelect 1GB 184-Pin DDR SDRAM Unbuffered DDR 400 (PC 3200)
System Memory - Retail"},
    {
      "id":"VDBDB1A16",
      "name":"A-DATA V-Series 1GB 184-Pin DDR SDRAM Unbuffered DDR 400 (PC 3200)
System Memory - OEM"},
    {
      "id":"0579B002",
      "name":"Canon PIXMA MP500 All-In-One Photo Printer"},
    {
      "id":"EN7800GTX/2DHTV/256M",
      "name":"ASUS Extreme N7800GTX/2DHTV (256 MB)"}]
  }
}

```

Grouping by Query

In this example, we will use the `group.query` parameter to find the top three results for "memory" in two different price ranges: 0.00 to 99.99, and over 100.

<http://localhost:8983/solr/select?wt=json&indent=true&fl=id,name,manufacturer&q=solr>

```

{
  "responseHeader":{
    "status":0,
    "QTime":42,
    "params":{
      "fl":"name,price",
      "indent":"true",
      "q":"memory",
      "group.limit":"3",
      "group.query":["price:[0 TO 99.99]",
        "price:[100 TO *]"],
      "group":"true",
      "wt":"json"}},
  "grouped":{
    "price:[0 TO 99.99]":{
      "matches":5,
      "doclist":{"numFound":1,"start":0,"docs":[
        {
          "name":"CORSAIR ValueSelect 1GB 184-Pin DDR SDRAM Unbuffered DDR 400 (PC
3200) System Memory - Retail",
          "price":74.99}
        ]}},
    "price:[100 TO *]":{
      "matches":5,
      "doclist":{"numFound":3,"start":0,"docs":[
        {
          "name":"CORSAIR XMS 2GB (2 x 1GB) 184-Pin DDR SDRAM Unbuffered DDR 400 (PC
3200) Dual Channel Kit System Memory - Retail",
          "price":185.0},
        {
          "name":"Canon PIXMA MP500 All-In-One Photo Printer",
          "price":179.99},
        {
          "name":"ASUS Extreme N7800GTX/2DHTV (256 MB)",
          "price":479.95}
        ]}}
    ]}
  }
}

```

In this case, Solr found five matches for "memory," but only returns four results grouped by price. This is because one result for "memory" did not have a price assigned to it.

Spell Checking

The SpellCheck component is designed to provide inline query suggestions based on other, similar, terms. The basis for these suggestions can be terms in a field in Solr, externally created text files, or fields in other Lucene indexes.

Topics covered in this section:

- [Configuring the SpellCheckComponent](#)
- [Spell Check Parameters](#)
- [Distributed SpellCheck](#)

Configuring the SpellCheckComponent

Define Spell Check in solrconfig.xml

The first step is to specify the source of terms in `solrconfig.xml`. Below is a simple example of how this would be done with the `IndexBasedSpellChecker`, which uses a field in Solr the basis of the spell check index:

```
<searchComponent name="spellcheck" class="solr.SpellCheckComponent">
  <lst name="spellchecker">
    <str name="classname">solr.IndexBasedSpellChecker</str>
    <str name="spellcheckIndexDir">./spellchecker</str>
    <str name="field">content</str>
    <str name="buildOnCommit">true</str>
  </lst>
</searchComponent>
```

The first element of that is to define the *searchComponent* to use the `solr.SpellCheckComponent`. The *classname* is the specific implementation of the `SpellCheckComponent`. In 3.4, there are 2 options: `IndexBasedSpellChecker`, which uses a field as the basis of the spell check terms; or `FileBasedSpellChecker`, which uses an external file as the basis of the terms. Defining the *classname* is optional; if not defined, it will default to `IndexBasedSpellChecker`.

The *spellcheckIndexDir* defines the location of the directory that holds the spellcheck index, while the *field* defines the source field (defined in `schema.xml`) for spell check terms. When choosing a field for the spellcheck index, it's best to avoid a heavily processed field to get more accurate results. If the field has many word variations from processing synonyms and/or stemming, the dictionary will be created with those variations in addition to more valid spelling data.

Finally, *buildOnCommit* defines whether to build the spell check index at every commit (i.e., every time new documents are added to the index) - it is optional, and can be omitted if you'd rather set it at false.

If using the `FileBasedSpellChecker`, you would define the `searchComponent` as so:

```
<searchComponent name="spellcheck" class="solr.SpellCheckComponent">
  <lst name="spellchecker">
    <str name="classname">solr.FileBasedSpellChecker</str>
    <str name="name">file</str>
    <str name="sourceLocation">spellings.txt</str>
    <str name="characterEncoding">UTF-8</str>
    <str name="spellcheckIndexDir">./spellcheckerFile</str>
  </lst>
</searchComponent>
```

The differences here are the use of the *sourceLocation* to define the location of the file of terms and the use of *characterEncoding* to define the encoding of the terms file.

-  In the above example, *name* is used to name this specific definition of the spellchecker. Multiple definitions can co-exist in a single `solrconfig.xml`, and the *name* helps to differentiate them when they are defined in the `schema.xml`. If only defining one spellchecker, no name is required.

Add It to a Request Handler

Queries will be sent to a [RequestHandler](#). If every request should generate a suggestion, then you would add the following to the `requestHandler` that you are using:

```
<str name="spellcheck">true</str>
```

 This section covers some of the basic implementation options for Spell Checking. For more advanced options, including how to buildOnOptimize, modify how terms are sorted, or customize how suggestions are made, see the page on the SpellCheckComponent[<http://wiki.apache.org/solr/SpellCheckComponent>] on the Solr Wiki.

Spell Check Parameters

The SpellCheck component accepts the parameters described in the table below.

Parameter	Description
spellcheck	Turns on or off SpellCheck suggestions for the request. If true , then spelling suggestions will be generated.
spellcheck.q or q	Selects the query to be spellchecked.
spellcheck.build	Instructs Solr to build a dictionary for use in spellchecking.
spellcheck.collate	Causes Solr to build a new query based on the best suggestion for each term in the submitted query.
spellcheck.maxCollations	This parameter specifies the maximum number of collations to return.
spellcheck.maxCollationTries	This parameter specifies the number of collation possibilities for Solr to try before giving up.
spellcheck.maxCollationEvaluations	This parameter specifies the maximum number of word correction combinations to rank and evaluate prior to deciding which collation candidates to test against the index.
spellcheck.collateExtendedResult	
spellcheck.count	Specifies the maximum number of spelling suggestions to be returned.
spellcheck.dictionary	Specifies the dictionary that should be used for spellchecking.

spellcheck.extendedResults	Causes Solr to return additional information about spellcheck results, such as the frequency of each original term in the index (<code>origFreq</code>) as well as the frequency of each suggestion in the index (<code>frequency</code>). Note that this result format differs from the non-extended one as the returned suggestion for a word is actually an array of lists, where each list holds the suggested term and its frequency.
spellcheck.onlyMorePopular	Limits spellcheck responses to queries that are more popular than the original query.
spellcheck.reload	Reloads the spellchecker.
spellcheck.accuracy	Specifies an accuracy value to help decide whether a result is worthwhile.
spellcheck.<DICT_NAME>.key	Specifies a key/value pair for the implementation handling a given dictionary.

The spellcheck Parameter

This parameter turns on SpellCheck suggestions for the request. If **true**, then spelling suggestions will be generated.

The spellcheck.q or q Parameter

This parameter specifies the query to spellcheck. If `spellcheck.q` is defined, then it is used; otherwise the original input query is used. The `spellcheck.q` parameter is intended to be the original query, minus any extra markup like field names, boosts, and so on. If the `q` parameter is specified, then the `SpellingQueryConverter` class is used to parse it into tokens; otherwise the `WhitespaceTokenizer` is used. The choice of which one to use is up to the application. Essentially, if you have a spelling "ready" version in your application, then it is probably better to use `spellcheck.q`. Otherwise, if you just want Solr to do the job, use the `q` parameter.

 The `SpellingQueryConverter` class does not deal properly with non-ASCII characters. In this case, you have either to use `spellcheck.q`, or implement your own `QueryConverter`.

The spellcheck.build Parameter

If set to **true**, this parameter creates the dictionary that the SolrSpellChecker will use for spell-checking. In a typical search application, you will need to build the dictionary before using the SolrSpellChecker. However, it's not always necessary to build a dictionary first. For example, you can configure the spellchecker to use a dictionary that already exists.

The dictionary will take some time to build, so this parameter should not be sent with every request.

The **spellcheck.reload** Parameter

If set to true, this parameter reloads the spellchecker. The results depend on the implementation of `SolrSpellChecker.reload()`. In a typical implementation, reloading the spellchecker means reloading the dictionary.

The **spellcheck.count** Parameter

This parameter specifies the maximum number of suggestions that the spellchecker should return for a term. If this parameter isn't set, the value defaults to 1. If the parameter is set but not assigned a number, the value defaults to 5. If the parameter is set to a positive integer, that number becomes the maximum number of suggestions returned by the spellchecker.

The **spellcheck.onlyMorePopular** Parameter

If **true**, Solr will to return suggestions that result in more hits for the query than the existing query. Note that this will return more popular suggestions even when the given query term is present in the index and considered "correct".

The **spellcheck.extendedResults** Parameter

This parameter causes to Solr to include additional information about the suggestion, such as the frequency in the index.

The **spellcheck.collate** Parameter

If **true**, this parameter directs Solr to take the best suggestion for each token (if one exists) and construct a new query from the suggestions. For example, if the input query was "jawa class lording" and the best suggestion for "jawa" was "java" and "lording" was "loading", then the resulting collation would be "java class loading".

The `spellcheck.collate` parameter only returns collations that are guaranteed to result in hits if re-queried, even when applying original `fq` parameters. This is especially helpful when there is more than one correction per query.

This only returns a query to be used. It does not actually run the suggested query.

The `spellcheck.maxCollations` Parameter

The maximum number of collations to return. The default is **1**. This parameter is ignored if `spellcheck.collate` is `false`.

The `spellcheck.maxCollationTries` Parameter

This parameter specifies the number of collation possibilities for Solr to try before giving up. Lower values ensure better performance. Higher values may be necessary to find a collation that can return results. The default value is `0`, which maintains backwards-compatible (Solr 1.4) behavior (do not check collations). This parameter is ignored if `spellcheck.collate` is `false`.

The `spellcheck.maxCollationEvaluations` Parameter

This parameter specifies the maximum number of word correction combinations to rank and evaluate prior to deciding which collation candidates to test against the index. This is a performance safety-net in case a user enters a query with many misspelled words. The default is **10,000** combinations, which should work well in most situations.

The `spellcheck.collateExtendedResult` Parameter

If **true**, this parameter returns an expanded response format detailing the collations Solr found. The default value is **false**. Ignored if `spellcheck.collate` is `false`. Following is an example of the extended output for the misspelled query `Title:(hopq AND faill)`:

```
<lst name="collation">
  <str name="collationQuery">Title:(hope AND faith)</str>
  <int name="hits">2</int>
  <lst name="misspellingsAndCorrections">
    <str name="hopq">hope</str>
    <str name="faill">faith</str>
  </lst>
</lst>
<lst name="collation">
  <str name="collationQuery">Title:(chops AND all)</str>
  <int name="hits">1</int>
  <lst name="misspellingsAndCorrections">
    <str name="hopq">chops</str>
    <str name="faill">all</str>
  </lst>
</lst>
```

The `spellcheck.dictionary` Parameter

This parameter causes Solr to use the dictionary named in the parameter's argument. The default setting is "default". This parameter can be used to invoke a specific spellchecker on a per request basis.

The `spellcheck.accuracy` Parameter

Specifies an accuracy value to be used by the spell checking implementation to decide whether a result is worthwhile or not. The value is a float between 0 and 1. Defaults to `Float.MIN_VALUE`.

The `spellcheck.<DICTIONARY_NAME>.key` Parameter

Specifies a key/value pair for the implementation handling a given dictionary. This key/value pair is passed through to the implementation in a `SolrParams` class. The value that is passed through is just `key=value` (`spellcheck.<DICTIONARY_NAME>.` is stripped off).

For example, given a dictionary called `foo`, `spellcheck.foo.myKey=myValue` would result in `myKey=myValue` being passed through to the implementation handling the dictionary `foo`.

Example

This example shows the results of a simple query that defines a query using the `spellcheck.q` parameter. The query also includes a `spellcheck.build=true` parameter, which is needed to be called only once in order to build the index. `spellcheck.build` should not be specified with for each request.

```
http://localhost:8983/solr/spellCheckCompRH?q=*:*&spellcheck.q=hell%20ultrashar&spel
```

Results:

```

<lst name="spellcheck">
  <lst name="suggestions">
    <lst name="hell">
      <int name="numFound">1</int>
      <int name="startOffset">0</int>
      <int name="endOffset">4</int>
      <arr name="suggestion">
        <str>dell</str>
      </arr>
    </lst>
    <lst name="ultrashar">
      <int name="numFound">1</int>
      <int name="startOffset">5</int>
      <int name="endOffset">14</int>
      <arr name="suggestion">
        <str>ultrasharp</str>
      </arr>
    </lst>
  </lst>
</lst>

```

Distributed SpellCheck

The `SpellCheckComponent` also supports spellchecking on distributed indexes. If you are using the `SpellCheckComponent` on a request handler other than `/select`, you must provide the following two parameters:

Parameter	Description
shards	Specifies the shards in your distributed indexing configuration. For more information about distributed indexing, see https://dev.lcimg.com/wiki/display/SRG34/Distributed+Search+with+Index+Sharding .
shards.qt	Specifies the request handler Solr uses for requests to shards. This parameter is not required for the <code>/select</code> request handler.

For example:

```
http://solr:8983/solr/select?q=*:*&spellcheck=true&spellcheck.build=true&spellcheck.
```

In case of a distributed request to the `SpellCheckComponent`, the shards are requested for at least five suggestions even if the `spellcheck.count` parameter value is less than five. Once the suggestions are collected, they are ranked by the configured distance measure (Levenstein Distance by default) and then by aggregate frequency.

Suggester

Solr includes an autosuggest component called Suggester, which is built on the [SpellCheck search component](#). The autocomplete suggestions that Suggester provides come from a dictionary that is based on the main index or on a dictionary file that you provide. It is common to provide only the top-N suggestions, either ranked alphabetically or according to their usefulness for an average user (such as popularity or the number of returned results).

Configuring Suggester

Because it is based on the [SpellCheck search component](#), configuring Suggester is very similar to configuring spell checking. In `solrconfig.xml`, add something like the following:

```

<searchComponent class="solr.SpellCheckComponent" name="suggest">
  <lst name="spellchecker">
    <str name="name">suggest</str>
    <str name="classname">org.apache.solr.spelling.suggest.Suggester</str>
    <str name="lookupImpl">org.apache.solr.spelling.suggest.tst.FSTLookup</str>
    <!-- Alternatives to lookupImpl:
      org.apache.solr.spelling.suggest.fst.FSTLookup  [finite state automaton]
      org.apache.solr.spelling.suggest.jaspell.JaspellLookup [default,
jaspell-based]
      org.apache.solr.spelling.suggest.tst.TSTLookup  [ternary trees]
    -->
    <str name="field">name</str> <!-- the indexed field to derive suggestions from
-->
    <float name="threshold">0.005</float>
    <str name="buildOnCommit">true</str>
  <!--
    <str name="sourceLocation">american-english</str>
  -->
  </lst>
</searchComponent>

<requestHandler class="org.apache.solr.handler.component.SearchHandler"
name="/suggest">
  <lst name="defaults">
    <str name="spellcheck">true</str>
    <str name="spellcheck.dictionary">suggest</str>
    <str name="spellcheck.onlyMorePopular">true</str>
    <str name="spellcheck.count">5</str>
    <str name="spellcheck.collate">true</str>
  </lst>
  <arr name="components">
    <str>suggest</str>
  </arr>
</requestHandler>

```

The look-up of matching suggestions in a dictionary is implemented by subclasses of the `lookup` class. Solr includes three `lookup` class implementations:

- `FSTLookup`: automaton based representation; slower to build, but consumes far less memory at runtime.
- `JaspellLookup`: tree-based representation based on Jaspell.
- `TSTLookup`: ternary tree based representation, capable of immediate data structure updates.

All three implementations will most likely run at similar speed when requests are made through HTTP. Direct benchmarks of these classes indicate that FSTLookup provides better performance compared to the other two methods, and at a much lower memory cost. We recommend using the FSTLookup implementation unless you need more sophisticated matching, in which case you should use the JaspellLookup implementation.

Suggester Parameters

Suggester Search Component Parameters

The Suggester search component takes the following configuration parameters:

Parameter	Description
searchComponent name	Arbitrary name for the search component.
name	A symbolic name for this spellchecker. You can refer to this name in the URL parameters and in the SearchHandler configuration.
classname	Suggester
lookupImpl	Lookup implementation. Choose one of these three: org.apache.solr.suggest.fst.FSTLookup : automaton-based lookup. This implementation provides the best performance and the lowest memory cost. We recommend using this implementation unless you need more sophisticated matching results, in which case you should use the Jaspell implementation. org.apache.solr.suggest.jaspell.JaspellLookup : a more complex lookup based on a ternary trie from the JaSpell project. Use this implementation if you need more sophisticated matching results. org.apache.solr.suggest.tst.TSTLookup : a simple compact ternary trie based lookup.

buildOnCommit	<p>False by default. If true then the Lookup data structure will be rebuilt after commit. If false, then the Lookup data will be built only when requested by URL parameter <code>spellcheck.build=true</code>.</p> <div style="border: 1px solid orange; background-color: #ffffcc; padding: 10px; margin-top: 10px;"> <p> Currently implemented Lookups keep their data in memory, so unlike spellchecker data, this data is discarded on core reload and not available until you invoke the build command, either explicitly or implicitly during a commit.</p> </div>
sourceLocation	The path to the dictionary file. If this value is empty then the main index will be used as a source of terms and weights.
field	If <code>sourceLocation</code> is empty then terms from this field in the index will be used when building the trie.
threshold	A value between zero and one representing the minimum fraction of the total documents where a term should appear in order to be added to the lookup dictionary.

Dictionary files should be plain text files in UTF-8 encoding. Blank lines and lines that start with a '#' are ignored. The remaining lines must consist of either a string without literal TAB (`\u0007`) characters, or a string and a TAB separated floating-point weight. You can use both single terms and phrases in a dictionary file.

```
# This is a sample dictionary file.

acquire
accidentally\t2.0
accommodate\t3.0
```

If weight is missing it's assumed to be 1.0. Weights affect the sorting of matching suggestions when `spellcheck.onlyMorePopular=true` is selected: weights are treated as "popularity" score, with higher weights preferred over suggestions with lower weights.

When you use the index as the dictionary, you may encounter many invalid or uncommon terms. The `threshold` parameter addresses this issue. By setting the `threshold` parameter to a value just above zero, you can greatly reduce the number of unusable terms in your dictionary while maintaining most of the common terms. The example above sets the `threshold` value to 0.5%. The `threshold` parameter does not affect file-based dictionaries.

Suggester Request Handler Parameters

The Suggester request handler takes the following configuration parameters:

Parameter	Description
spellcheck=true	This parameter should always be true, because we always want to run the Suggester for queries submitted to this handler.
spellcheck.dictionary	The name of the dictionary component configured in the search component.
spellcheck.onlyMorePopular	If true, then suggestions will be sorted by weight ("popularity"). The <code>count</code> parameter will effectively limit this to a top-N list of best suggestions. If false, suggestions are sorted alphabetically.
spellcheck.count	Specifies the number of suggestions for Solr to return.
spellcheck.collate	If true, Solr provides a query collated with the first matching suggestion.

Spatial Search

Solr supports location data for use in spatial or geospatial searches. Using spatial search, you can:

- Represent spatial data in the index
- Filter by location based on a bounding box or circle
- Sort by distance
- Score and boost by distance

There are three new function queries that support spatial search: `dist`, to determine the distance between two points; `hsin`, to calculate the distance between two points on a sphere; and `sqedist`, to calculate the square Euclidean distance between two points. For more information about these function queries, see [Function Queries](#) and <http://wiki.apache.org/solr/FunctionQuery>.

For more information on Solr spatial search, see <http://wiki.apache.org/solr/SpatialSearch>.

Spatial Search Features

Solr includes three useful tools for working with spatial queries: `geofilt`, a geospatial filter; `bbox`, a geospatial bounding-box filter; and `geodist`, a geospatial distance function.

Spatial Search Parameters

The following parameters are used for spatial search:

Parameter	Description
<code>d</code>	distance, in kilometers
<code>pt</code>	a lat/lon coordinate point
<code>sfield</code>	a spatial field, by default a <code>location</code> (lat/lon) field type.

geofilt

The `geofilt` filter allows you to retrieve results based on the distance from a given point. For example, to find all results for a product search within five kilometers of the lat/lon point, you could enter `...&q= : &fq={!geofilt sfield=store}&pt=45.15,-93.85&d=5`. This filter returns all results within a circle of the given radius around the initial point:

bbox

`bbox` allows you to filter results based on a specified area around a given point. `bbox` takes the same parameters as `geofilt`, but rather than calculating all points in a circle within the given radius from the initial point, it only calculates the lower left and upper right corners of a square that would enclose a circle with the given radius. To return all results within five kilometers of a give point, you could enter `...&q= : &fq={!bbox sfield=store}&pt=45.15,-93.85&d=5`. The resulting bounding box would encompass all points within a five kilometer circle around the initial point, but it would also include some extra points in the corners of the bounding box that fall outside the five kilometer radius. Bounding box filters therefore can return results that fall outside your desired parameters, but they are much less "expensive" to implement.

⚠ When a bounding box includes a pole, the `location` field type produces a "bounding bowl" (a spherical cap) that includes all values that are north or south of the latitude of the bounding box corner (the lower left and the upper right) that is closer to the equator. In other words, Solr still calculates what the coordinates of the upper right corner and the lower left corner of the box would be just as in all other filtering cases, but it then take the corner that is closest to the equator (since it goes over the pole it may not be the lower left, despite the name) and filters by latitude only. This returns more matches than a pure bounding box match, but the query is both faster and easier to construct.

geodist

`geodist` is a distance function that takes three optional parameters:

(`sfield`, `latitude`, `longitude`). You can use the `geodist` function to sort results by distance or score return results.

For example, to sort your results by ascending distance, you could enter `...&q= : &fq={!geofilt }&sfield=store&pt=45.15,-93.85&d=50&sort=geodist asc`.

To return the distance as the document score, you could enter `...&q={!func} geodist%28%29&sfield=store&pt=45.15,-93.85&sort=score+asc`.

More Examples

Here are a few more useful examples of what you can do with spatial search in Solr.

Use as a Sub-Query to Expand Search Results

Here we will query for results in Jacksonville, Florida, or within 50 kilometers of 45.15,-93.85 (near Buffalo, Minnesota):

```
...&q= : &fq=(state:"FL" AND city:"Jacksonville") OR query : "{!geofilt}
"&sfield=store&pt=45.15,-93.85&d=50&sort=geodist() asc
```

Facet by Distance

To facet by distance, use the Frange query parser:

```
...&q= : &sfield=store&pt=45.15,-93.85&facet.query={!frange l=0 u=5}
geodist()&facet.query={!frange l=5.001 u=3000}geodist()
```

Boost Nearest Results

Using the [DisMax](#) or [Extended DisMax](#), you can combine spatial search with the boost function to boost the nearest results:

```
...&q.alt= : &fq={!geofilt}
&sfield=store&pt=45.15,-93.85&d=50&bf=recip(geodist(),2,200,20)&sort=score desc
```

The Terms Component

The Terms Component provides access to the indexed terms in a field and the number of documents that match each term. This can be useful for building an auto-suggest feature or any other feature that operates at the term level instead of the search or document level. Retrieving terms in index order is very fast since the implementation directly uses Lucene's TermEnum to iterate over the term dictionary.

In a sense, this component provides fast field-faceting over the whole index, not restricted by the base query or any filters. The document frequencies returned are the number of documents that match the term, including any documents that have been marked for deletion but not yet removed from the index.

To use the Terms Component, users can pass in a variety of options to control what terms are returned. The supported parameters are available in the class:

<http://lucene.apache.org/solr/api/org/apache/solr/common/params/TermsParams.html>

These parameters are:

Parameter	Description	Syntax
terms	If set to true, terms on the Terms Component. By default, the Terms Component is turned off.	terms={true false}
terms.fl	Specifies the field from which to retrieve terms.	terms.fl= field
terms.lower	Specifies the term at which to start. If not specified, the empty string is used, causing Solr to start at the beginning of the field.	terms.lower= term
terms.lower.incl	If set to true, includes the lower-bound term in the result set. By default, this parameter is set to true.	terms.lower.incl={true false}
terms.mincount	Specifies the minimum document frequency to return in order for a term to be included in a query response. Results are inclusive of the mincount (that is, \geq mincount). This parameter is optional.	terms.mincount= integer

<code>terms.maxcount</code>	Specifies the maximum document frequency a term must have in order to be included in a query response. The default setting is -1, which sets no upper bound. Results are inclusive of the maxcount (that is, \leq maxcount). This parameter is optional.	<code>terms.maxcount= integer</code>
<code>terms.prefix</code>	Restricts matches to terms that begin with the specified string.	<code>terms.prefix={string}</code>
<code>terms.limit</code>	Specifies the maximum number of terms to return. The default is 10. If the limit is set to a number less than 0, then no maximum limit is enforced.	<code>terms.limit= integer</code>
<code>terms.upper</code>	Specifies the term to stop at. Any application using the Terms component must set either <code>terms.limit</code> or <code>terms.upper</code> .	<code>terms.upper= upper_term</code>
<code>terms.upper.incl</code>	If set to true, includes the upper bound term in the result set. The default is false.	<code>terms.upper.incl={true false}</code>
<code>terms.raw</code>	If set to true, returns the raw characters of the indexed term, regardless of whether it is human-readable. For instance, the indexed form of numeric numbers is not human-readable. The default is false.	<code>terms.raw={true false}</code>

The output is a list of the terms and their document frequency values.

Examples

The following examples use the sample Solr configuration located in the `<Solr>/example` directory.

The query below requests the first ten terms in the name field.

```
http://localhost:8983/solr/terms?terms.fl=name
```

Results:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
<lst name="responseHeader">
  <int name="status">0</int>
  <int name="QTime">1</int>
</lst>
<lst name="terms">
  <lst name="name">
    <int name="0">5</int>
    <int name="1">15</int>
    <int name="11">5</int>
    <int name="120">5</int>
    <int name="133">5</int>
    <int name="184">15</int>
    <int name="19">5</int>
    <int name="1900">5</int>
    <int name="2">15</int>
    <int name="20">5</int>
  </lst>
</lst>
</response>
```

The query below requests the first ten terms in the name field, beginning with the first term that begins with the letter a.

<http://localhost:8983/solr/terms?terms.fl=name&terms.lower=a>

Results:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
<lst name="responseHeader">
  <int name="status">0</int>
  <int name="QTime">2</int>
</lst>
<lst name="terms">
  <lst name="name">
    <int name="a">8</int>
    <int name="adata">5</int>
    <int name="all">5</int>
    <int name="allinon">5</int>
    <int name="amber">1</int>
    <int name="appl">5</int>
    <int name="asus">5</int>
    <int name="ata">5</int>
    <int name="ati">5</int>
    <int name="b">5</int>
  </lst>
</lst>
</response>
```

Using the Terms Component for an Auto-Suggest Feature

If the [Suggester](#) doesn't suit your needs, you can use the Terms component in Solr to build a similar feature for your own search application. Simply submit a query specifying whatever characters the user has typed so far as a prefix. For example, if the user has typed "at", the search engine's interface would submit the following query:

```
http://localhost:8983/solr/terms?terms.fl=name&terms.prefix=at
```

Result:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
<lst name="responseHeader">
  <int name="status">0</int>
  <int name="QTime">120</int>
</lst>
<lst name="terms">
  <lst name="name">
    <int name="ata">5</int> <int name="ati">5</int>
  </lst>
</lst>
</response>
```

You can use the parameter `omitHeader=true` to omit the response header from the query response, like so:

`http://localhost:8983/solr/terms?terms.fl=name&terms.prefix=at&indent=true&wt=json&o`

Result:

```
{
  "terms": [
    "name", [
      "ata", 1,
      "ati", 1]]}
```

Distributed Search Support

The TermsComponent also supports distributed indexes. For the `/terms` request handler, you must provide the following two parameters:

Parameter	Description
shards	Specifies the shards in your distributed indexing configuration. For more information about distributed indexing, see https://dev.lcimg.com/wiki/display/SRG34/Distributed+Search+with+Index+Sharding
shards.qt	Specifies the request handler Solr uses for requests to shards.

The Term Vector Component

The Term Vector Component (TVC) is a search component designed to return information about documents. For each document, the TVC can return the term vector, the term frequency, inverse document frequency, position, and offset information. The TVC is stored when setting the `termVector` attribute on a field:

```
<field name="features"
  type="text"
  indexed="true"
  stored="true"
  multiValued="true"
  termVectors="true"
  termPositions="true"
  termOffsets="true"/>
```

As with most components, there are a number of options that are outlined in the samples below. All examples are based on the Solr example.

Enabling the the TermVectorComponent

Changes for solrconfig.xml

To enable the Term VectorComponent, you need to configure a `searchComponent` element in your `solrconfig.xml` file, like so:

```
<searchComponent name="tvComponent"
class="org.apache.solr.handler.component.TermVectorComponent"/>
```

A request handler configuration using this component could look like this:

```
<requestHandler name="tvrh" class="org.apache.solr.handler.component.SearchHandler">
  <lst name="defaults">
    <bool name="tv">true</bool>
  </lst>
  <arr name="last-components">
    <str>tvComponent</str>
  </arr>
</requestHandler>
```

Invoking the Term Vector Component

The example below shows an invocation of this component:

`http://localhost:8983/solr/select/?q=%3A*&version=2.2&start=0&rows=10&indent=on&qt=`

In the example, the component is associated with a request handler named `tvrh`, but you can associate it with any request handler. To turn on the component for a request, add the `tv=true` parameter (or add it to your RequestHandler defaults configuration).

Example output: See <http://wiki.apache.org/solr/TermVectorComponentExampleEnabled>

Optional Parameters

The example below shows optional parameters for this component:

`http://localhost:8983/solr/select/?q=%3A*&version=2.2&start=0&rows=10&indent=on&qt=`

Boolean Parameters	Description
<code>tv.all</code>	A shortcut that invokes all the parameters listed below.
<code>tv.df</code>	Returns the Document Frequency (DF) of the term in the collection. This can be computationally expensive.
<code>tv.offsets</code>	Returns offset information for each term in the document.
<code>tv.positions</code>	Returns position information.
<code>tv.tf</code>	Returns document term frequency info per term in the document.
<code>tv.tf_idf</code>	Calculates TF*IDF for each term. Requires the parameters <code>tv.tf</code> and <code>tv.df</code> to be "true". This can be computationally expensive. (The results are not shown in example output)

To learn more about TermVector component output, see the Wiki page:

<http://wiki.apache.org/solr/TermVectorComponentExampleOptions>

For schema requirements, see the Wiki page: <http://wiki.apache.org/solr/FieldOptionsByUseCase>

The Term Vector component also accepts these optional parameters:

Parameters	Description
<code>tv.docIds</code>	Returns term vectors for the specified list of Lucene document IDs (not the Solr Unique Key).
<code>tv.fl</code>	Returns term vectors for the specified list of fields. If not specified, the <code>f1</code> parameter is used.

SolrJ and the Term Vector Component

Neither the SolrQuery class nor the QueryResponse class offer specific method calls to set Term Vector Component parameters or get the "termVectors" output. However, there is a patch for it: [SOLR-949](#).

The Stats Component

The Stats component returns simple statistics for numeric fields within the document set.

Stats Component Parameters

The Stats Component accepts the following parameters:

Parameter	Description
stats	If true , then invokes the Stats component.
stats.field	Specifies a field for which statistics should be generated. This parameter may be invoked multiple times in a query in order to request statistics on multiple fields. (See the example below.)
stats.facet	Returns sub-results for values within the specified facet.

Statistics Returned

The table below describes the statistics returned by the Stats component.

Name	Description
min	The minimum value in the field.
max	The maximum value in the field.
sum	The sum of all values in the field.
count	The number of non-null values in the field.
missing	The number of null values in the field.
sumOfSquares	Sum of all values squared (useful for <code>stddev</code>).
mean	The average $(v_1 + v_2 + \dots + v_N)/N$
stddev	Standard deviation, measuring how widely spread the values in the data set are.

Example

The query below:

```
http://localhost:8983/solr/select?q=*&stats=true&stats.field=price&stats.field=pop
```

Would produce the following results:

```
<lst name="stats">
  <lst name="stats_fields">
    <lst name="price">
      <double name="min">0.0</double>
      <double name="max">2199.0</double>
      <double name="sum">5251.2699999999995</double>
      <long name="count">15</long>
      <long name="missing">11</long>
      <double name="sumOfSquares">6038619.160300001</double>
      <double name="mean">350.08466666666664</double>
      <double name="stddev">547.737557906113</double>
    </lst>
    <lst name="popularity">
      <double name="min">0.0</double>
      <double name="max">10.0</double>
      <double name="sum">90.0</double>
      <long name="count">26</long>
      <long name="missing">0</long>
      <double name="sumOfSquares">628.0</double>
      <double name="mean">3.4615384615384617</double>
      <double name="stddev">3.5578731762756157</double>
    </lst>
  </lst>
</lst>
```

Here are the same results with faceting requested for the field `inStock`, using the parameter `&stats.facet=inStock`.

```

<lst name="{*}stats{*}">
  <lst name="{*}stats{*}_fields">
    <lst name="price">
      <double name="min">0.0</double>
      <double name="max">2199.0</double>
      <double name="sum">5251.2699999999995</double>
      <long name="count">15</long>
      <long name="missing">11</long>
      <double name="sumOfSquares">6038619.160300001</double>
      <double name="mean">350.08466666666664</double>
      <double name="stddev">547.737557906113</double>
    <lst name="facets">
      <lst name="inStock">
        <lst name="false">
          <double name="min">11.5</double>
          <double name="max">649.99</double>
          <double name="sum">1161.39</double>
          <long name="count">4</long>
          <long name="missing">0</long>
          <double name="sumOfSquares">653369.2551</double>
          <double name="mean">290.3475</double>
          <double name="stddev">324.63444676281654</double>
        </lst>
        <lst name="true">
          <double name="min">0.0</double>
          <double name="max">2199.0</double>
          <double name="sum">4089.8799999999999</double>
          <long name="count">11</long>
          <long name="missing">0</long>
          <double name="sumOfSquares">5385249.905200001</double>
          <double name="mean">371.8072727272727</double>
          <double name="stddev">621.6592938755265</double>
        </lst>
      </lst>
    </lst>
  </lst>
</lst>

```

The Stats Component and Faceting

The facet field can be selectively applied. That is if you want stats on field "A" and "B", you can facet a on "X" and B on "Y" using the parameters:

```
&stats.field=A&f.A.stats.facet=X&stats.field=B&f.B.stats.facet=Y
```

All facet results are returned, so be careful what fields you ask for.

Multi-valued fields and facets may be slow.

Multi-value fields rely on `UnInvertedField.java` for implementation. This is like a `FieldCache`, so be aware of your memory footprint.

The Query Elevation Component

The [Query Elevation Component](#) enables you to configure the top results for a given query regardless of the normal Lucene scoring. This is sometimes called "sponsored search," "editorial boosting," or "best bets." This component matches the user query text to a configured map of top results. Although this component will work with any `QueryParser`, it makes the most sense to use with [DisMax](#) or [eDisMax](#).

Configuring the Query Elevation Component

You can configure the Query Elevation Component in the `solrconfig.xml` file. The default configuration looks like this:

```
<searchComponent name="elevator" class="solr.QueryElevationComponent" >
  <!-- pick a fieldType to analyze queries -->
  <str name="queryFieldType">string</str>
  <str name="config-file">elevate.xml</str>
</searchComponent>

<requestHandler name="/elevate" class="solr.SearchHandler" startup="lazy">
  <lst name="defaults">
    <str name="echoParams">explicit</str>
  </lst>
  <arr name="last-components">
    <str>elevator</str>
  </arr>
</requestHandler>
```

The Query Elevation Search Component takes the following arguments:

Argument	Description
queryFieldType	Specifies which fieldType should be used to analyze the incoming text. For example, it may be appropriate to use a fieldType with a LowerCaseFilter.
config-file	Path to the file that defines query elevation. This file must exist in <code>\${instanceDir}/conf/\${config-file}</code> or <code>\${dataDir}/\${config-file}</code> . If the file exists in the <code>/conf/</code> directory it will be loaded once at startup. If it exists in the data directory, it will be reloaded for each <code>IndexReader</code> .

forceElevation	By default, this component respects the requested <code>sort</code> parameter: if the request asks to sort by date, it will order the results by date. If <code>forceElevation=true</code> , results will first return the boosted docs, then order by date.}}
----------------	--

elevate.xml

Elevated query results are configured in an external XML file specified in the `config-file` argument. An `elevate.xml` file might look like this:

```
<elevate>
  <query text="AAA">
    <doc id="A" />
    <doc id="B" />
  </query>

  <query text="ipod">
    <doc id="A" />

    <!-- you can optionally exclude documents from a query result -->

    <doc id="B" exclude="true" />
  </query>
</elevate>
```

In this example, the query "AAA" would first return documents A and B, then whatever normally appears for the same query. For the query "ipod", it would first return A, and would make sure that B is not in the result set.

The `uniqueKey` field must currently be of type `string` for the `QueryElevationComponent` to operate properly.

Using the Query Elevation Component

The `enableElevation` Parameter

For debugging it may be useful to see results with and without the elevated docs. To hide results, use `enableElevation=false`:

```
http://localhost:8983/solr/elevate?q=YYYY&debugQuery=true&enableElevation=true
```

```
http://localhost:8983/solr/elevate?q=YYYY&debugQuery=true&enableElevation=false
```

The forceElevation Parameter

You can force elevation during runtime by adding `forceElevation=true` to the query URL:

```
http://localhost:8983/solr/elevate?q=YYYY&debugQuery=true&enableElevation=true&force
```

The exclusive Parameter

You can force Solr to return only the results specified in the elevation file by adding `exclusive=true` to the URL:

```
http://localhost:8983/solr/elevate?q=YYYY&debugQuery=true&exclusive=true
```

The fq Parameter

Query elevation respects the standard filter query (`fq`) parameter. That is, if the query contains the `fq` parameter, all results will be within that filter even if `elevate.xml` adds other documents to the result set.

Response Writers

A Response Writer generates the formatted response of a search. Solr supports a variety of Response Writers to ensure that query responses can be parsed by the appropriate language or application.

The `wf` parameter selects the Response Writer to be used. The table below lists the most common settings for the `wf` parameter.

<code>wf</code> Parameter Setting	Response Writer Selected
csv	CSVResponseWriter
json	JSONResponseWriter
php	PHPResponseWriter
phps	PHPSerializedResponseWriter
python	PythonResponseWriter
ruby	RubyResponseWriter
xml	XMLResponseWriter
xslt	XSLTResponseWriter

The Standard XML Response Writer

The XML Response Writer is the most general purpose and reusable Response Writer currently included with Solr. It is the format used in most discussions and documentation about the response of Solr queries.

Note that the XSLT Response Writer can be used to convert the XML produced by this writer to other vocabularies or text-based formats.

The behavior of the XML Response Writer can be driven by the following query parameters.

The version Parameter

The `version` parameter determines the XML protocol used in the response. Clients are strongly encouraged to *always* specify the protocol version, so as to ensure that the format of the response they receive does not change unexpectedly when the Solr server is upgraded.

XML Version	Notes
-------------	-------

2.0	An <code><arr></code> tag was used for multiValued fields only if there was more than one value.
2.1	An <code><arr></code> tag is used for multiValued fields even if there is only one value.
2.2	The format of the responseHeader changed to use the same <code><lst></code> structure as the rest of the response.

The default value is the latest supported.

The stylesheet Parameter

The `stylesheet` parameter can be used to direct Solr to include a `<?xml-stylesheet type="text/xsl" href="..."?>` declaration in the XML response it returns.

The default behavior is not to return any stylesheet declaration at all.

 Use of the `stylesheet` parameter is discouraged, as there is currently no way to specify external stylesheets, and no stylesheets are provided in the Solr distributions. This is a legacy parameter, which may be developed further in a future release.

The indent Parameter

If the `indent` parameter is used, and has a non-blank value, then Solr will make some attempts at indenting its XML response to make it more readable by humans.

The default behavior is not to indent.

The XSLT Response Writer

The XSLT Response Writer applies an XML stylesheet to output. It can be used for tasks such as formatting results for an RSS feed.

tr Parameter

The XSLT Response Writer accepts one parameter: the `tr` parameter, which identifies the XML transformation to use. The transformation must be found in the Solr `conf/xslt` directory.

The Content-Type of the response is set according to the `<xsl:output>` statement in the XSLT transform, for example: `<xsl:output media-type="text/html"/>`

Configuration

The example below, from the default `solrconfig.xml` file, shows how the XSLT Response Writer is configured.

```
<!--
  Changes to XSLT transforms are taken into account
  every xsltCacheLifetimeSeconds at most.
-->
<queryResponseWriter
  name="xslt"
  class="org.apache.solr.request.XSLTResponseWriter"
>
  <int name="xsltCacheLifetimeSeconds">5</int>
</queryResponseWriter>
```

A value of 5 for `xsltCacheLifetimeSeconds` is good for development, to see XSLT changes quickly. For production you probably want a much higher value.

JSON Response Writer

A very commonly used Response Writer is the `JsonResponseWriter`, which formats output in JavaScript Object Notation (JSON), a lightweight data interchange format specified in RFC 4627. Setting the `wt` parameter to `json` invokes this Response Writer.

Python Response Writer

Solr has an optional Python response format that extends its JSON output in the following ways to allow the response to be safely evaluated by the python interpreter:

- true and false changed to True and False
- Python unicode strings are used where needed
- ASCII output (with unicode escapes) is used for less error-prone interoperability
- newlines are escaped
- null changed to None

PHP Response Writer and PHP Serialized Response Writer

Solr has a PHP response format that outputs an array (as PHP code) which can be evaluated. Setting the `wt` parameter to `php` invokes the PHP Response Writer.

Example usage:

```
$code = file_get_contents('http://localhost:8983/solr/select?q=iPod&wt={*}php{*}');
eval("$result = " . $code . ";");
print_r($result);
```

Solr also includes a PHP Serialized Response Writer that formats output in a serialized array. Setting the `wt` parameter to `phps` invokes the PHP Serialized Response Writer.

Example usage:

```
$serializedResult =
file_get_contents('http://localhost:8983/solr/select?q=iPod&wt={*}php{*}s');
$result = unserialize($serializedResult);
print_r($result);
```

Before you use either the PHP or Serialized PHP Response Writer, you may first need to un-comment these two lines in `solrconfig.xml`:

```
<queryResponseWriter name="php" class="org.apache.solr.request.PHPResponseWriter"/>
<queryResponseWriter name="phps"
class="org.apache.solr.request.PHPSerializedResponseWriter"/>
```

Ruby Response Writer

Solr has an optional Ruby response format that extends its JSON output in the following ways to allow the response to be safely evaluated by Ruby's interpreter:

- Ruby's single quoted strings are used to prevent possible string exploits.
- `\` and `'` are the only two characters escaped.
- Unicode escapes are not used. Data is written as raw UTF-8.
- `nil` used for null.
- `=>` is used as the key/value separator in maps.

Here is a simple example of how one may query Solr using the Ruby response format:

```
require 'net/http'
h = Net::HTTP.new('localhost', 8983)
hresp, data = h.get('/solr/select?q=iPod&wt=ruby', nil)
rsp = eval(data)
puts 'number of matches = ' + rsp['response']['numFound'].to_s
#print out the name field for each returned document
rsp['response']['docs'].each { |doc| puts 'name field = ' + doc['name'] }
```

CSV Response Writer

The CSV response writer returns a list of documents in comma-separated values (CSV) format. Other information that would normally be included in a response, such as facet information, is excluded.

The CSV response writer supports multi-valued fields, and the output of this CSV format is compatible with Solr's [CSV update format](#).

CSV Parameters

These parameters specify the CSV format that will be returned. You can accept the default values or specify your own.

Parameter	Default Value
csv.encapsulator	"
csv.escape	None
csv.separator	,
csv.header	Defaults to true. If false, Solr does not print the column headers
csv.newline	\n
csv.null	Defaults to a zero length string. Use this parameter when a document has no value for a particular field.

Multi-Valued Field CSV Parameters

These parameters specify how multi-valued fields are encoded. Per-field overrides for these values can be done using `f.<fieldname>.csv.separator=|`.

Parameter	Default Value
csv.mv.encapsulator	None
csv.mv.escape	\
csv.mv.separator	Defaults to the <code>csv.separator</code> value

Example

`http://localhost:8983/solr/select?q=ipod&fl=id,cat,name,popularity,price,score&wt=cs`
returns:

```
id,cat,name,popularity,price,score
IW-02,"electronics,connector",iPod & iPod Mini USB 2.0 Cable,1,11.5,0.98867977
F8V7067-APL-KIT,"electronics,connector",Belkin Mobile Power Cord for iPod w/
Dock,1,19.95,0.6523595
MA147LL/A,"electronics,music",Apple 60 GB iPod with Video Playback
Black,10,399.0,0.2446348
```

Binary Response Writer

Solr also includes a Response Writer that outputs binary format for use with a Java client. See [Client APIs](#) for more details.

The Well-Configured Solr Instance

This section tells you how to fine-tune your Solr instance for optimum performance. This section covers the following topics:

[Configuring solrconfig.xml](#): Describes how to work with the main configuration file for Solr.

[Configuring solr.xml](#): Describes how to configure your Solr core, or multiple Solr cores within a single instance.

[Lucene IndexWriters](#): Describes how to configure the index writers in the underlying Lucene engine.

[HTTP Request Dispatcher](#): Describes how to configure Solr's response to HTTP requests

[JVM Settings](#): Gives some guidance on best practices for working with Java Virtual Machines.

The focus of this section is on configuring a single Solr instance. To scale a Solr implementation, either through sharding or replication, please see [Scaling and Distribution](#).

For more information about factors affecting Solr performance, see <http://wiki.apache.org/solr/SolrPerformanceFactors>.

Configuring solrconfig.xml

The `solrconfig.xml` file is the configuration file with the most parameters affecting Solr itself. The file comprises a series of XML statements that set configuration values. In `solrconfig.xml`, you configure important features such as:

- request handlers
- listeners (processes that "listen" for particular query-related events; listeners can be used to trigger the execution of special code, such as invoking some common queries to warm-up caches)
- the Request Dispatcher for managing HTTP communications
- the Admin Web interface
- parameters related to replication and duplication (these parameters are covered in detail in [Scaling and Distribution](#))

The `solrconfig.xml` file is found in the `solr/conf/` directory.

For more information about `solrconfig.xml`, see <http://wiki.apache.org/solr/SolrConfigXml>.

Topics covered in this section:

- [Specifying a Location for Index Data with the `dataDir` Parameter](#)
- [Specifying the DirectoryFactory For Your Index](#)
- [Configuring the Lucene IndexWriters](#)
- [Controlling the Behavior of the Update Handler](#)
- [Query Settings in solrconfig.xml](#)
- [HTTP RequestDispatcher Settings](#)

Specifying a Location for Index Data with the `dataDir` Parameter

By default, Solr stores its index data in a directory called `/data` under the Solr home. If you would like to specify a different directory for storing index data, use the `<dataDir>` parameter in the `solrconfig.xml` file. You can specify another directory either with a full pathname or a pathname relative to the current working directory of the servlet container. For example:

```
<dataDir>/var/data/solr/</dataDir>
```

If you are using replication to replicate the Solr index (as described in [Scaling and Distribution](#)), then the `<dataDir>` directory should correspond to the index directory used in the replication configuration.

Specifying the DirectoryFactory For Your Index

The default `solr.StandardDirectoryFactory` is filesystem based, and tries to pick the best implementation for the current JVM and platform. You can force a particular implementation by specifying `solr.MMapDirectoryFactory`, `solr.NIOFSDirectoryFactory`, or `solr.SimpleFSDirectoryFactory`.

```
<directoryFactory name="DirectoryFactory"
                  class="{solr.directoryFactory:solr.StandardDirectoryFactory}"/>
```

The `solr.RAMDirectoryFactory` is memory based, not persistent, and does not work with replication. Use this DirectoryFactory to store your index in RAM.

```
<directoryFactory class="org.apache.solr.core.RAMDirectoryFactory"/>
```

Configuring the Lucene IndexWriters

The settings in this section are specified in the `<indexDefaults>` element in `solrconfig.xml` and control the behavior of Lucene index writers.

```
<indexDefaults>
  ...
</indexDefaults>
```

UseCompoundFile

Setting `<useCompoundFile>` to **true** combines the various files on disk that make up an index into a single file. On systems where the number of open files allowed per process is limited, setting this to true may avoid hitting that limit (the open files limit might also be tunable for your OS with the Linux/Unix `ulimit` command, or something similar for other operating systems).

Updating a compound index may incur a minor performance hit for various reasons, depending on the runtime environment. For example, filesystem buffers are typically associated with open file descriptors, which may limit the total cache space available to each index.

This setting may also affect how much data needs to be transferred during index replication operations.

This setting is **false** in the `solrconfig.xml` file for the example application. Since Lucene 1.4, the default in the code is **true**, if not explicitly specified.

```
<useCompoundFile>
false
</useCompoundFile>
```

mergeFactor

The `mergeFactor` controls how many segments a Lucene index is allowed to have before it is coalesced into one segment. When an update is made to an index, it is added to the most recently opened segment. When that segment fills up (see [maxBufferedDocs](#) and [ramBufferSizeMB](#) in the next section), a new segment is created and subsequent updates are placed there.

If creating a new segment would cause the number of lowest-level segments to exceed the `mergeFactor` value, then all those segments are merged together to form a single large segment. Thus, if the merge factor is ten, each merge results in the creation of a single segment that is roughly ten times larger than each of its ten constituents. When there are `mergeFactor` settings for these larger segments, then they in turn are merged into an even larger single segment. This process can continue indefinitely.

Choosing the best merge factor is generally a trade-off of indexing speed vs. searching speed. Having fewer segments in the index generally accelerates searches, because there are fewer places to look. It also can also result in fewer physical files on disk. But to keep the number of segments low, merges will occur more often, which can add load to the system and slow down updates to the index.

Conversely, keeping more segments can accelerate indexing, because merges happen less often - making an update is less likely to trigger a merge. But searches become more computationally expensive and will likely be slower, because search terms must be looked up in more index segments. Faster index updates also means shorter commit turnaround times, which means more timely search results.

The default value in the example `solrconfig.xml` is 10, which is a reasonable starting point.

```
<mergeFactor>
10
</mergeFactor>
```

Other Indexing Settings

There are a few other parameters that may be important to configure for your implementation. These settings affect how or when updates are made to an index.

Setting	Description
maxBufferedDocs	Sets the number of document updates to buffer in memory before flushed to disk and added to the current index segment. If the segment fills up, a new one may be created, or a merge may be started. The default Solr configuration leaves this value undefined.
ramBufferSizeMB	Once accumulated document updates exceed this much memory space (specified in megabytes), then the pending updates are flushed. This can also create new segments or trigger a merge. Using this setting is generally preferable to maxBufferedDocs. If both maxBufferedDocs and ramBufferSizeMB are set in solrconfig.xml, then a flush will occur when either limit is reached.
maxMergeDocs	This sets the maximum number of documents for a single segment. If this limit is reached, the segment is closed and a new segment is created. A merge, as governed by mergeFactor may also occur.
maxFieldLength	This determines the maximum number of terms that will be stored for a field. If field analysis generates more than the number of indexable tokens specified by this parameter, the excess tokens are discarded. Raising this limit too high can degrade performance because long term lists require more resources and take longer to traverse. Choose this value according to the needs of your application.

```
<maxBufferedDocs>1000</maxBufferedDocs>
<ramBufferSizeMB>32</ramBufferSizeMB>
<maxMergeDocs>2147483647</maxMergeDocs>
<maxFieldLength>10000</maxFieldLength>
```

Controlling the Behavior of the Update Handler

The settings in this section are configured in the `<updateHandler>` element in `solrconfig.xml` and may affect the performance of index updates. These settings affect how updates are done internally. `<updateHandler>` configurations do not affect the higher level configuration of RequestHandlers that process client update requests.

```
<updateHandler class="solr.DirectUpdateHandler2">
  ...
</updateHandler>
```

autoCommit

These settings control how often pending updates will be automatically pushed to the index.

Setting	Description
maxDocs	The number of updates that have occurred since the last commit.
maxTime	The number of milliseconds since the oldest uncommitted update.

If either of these limits are reached, then Solr automatically performs a commit operation. If the `autoCommit` tag is missing, then only explicit commits will update the index. The decision whether to use auto-commit or not depends on the needs of your application.

Determining the best auto-commit settings is a tradeoff between performance and accuracy. Settings that cause frequent updates will improve the accuracy of searches because new content will be searchable more quickly, but performance may suffer because of the frequent updates. Less frequent updates may improve performance but it will take longer for updates to show up in queries.

```
<autoCommit>
  <maxDocs>10000</maxDocs>
  <maxTime>1000</maxTime>
</autoCommit>
```

maxPendingDeletes

This value sets a limit on the number of deletions that Solr will buffer during document deletion. This can affect how much memory is used during indexing.

```
<maxPendingDeletes>
100000
</maxPendingDeletes>
```

Query Settings in solrconfig.xml

The settings in this section affect the way that Solr will process and respond to queries. These settings are all configured in child elements of the `<query>` element in `solrconfig.xml`.

```
<query>
  ...
</query>
```

Caching

Solr caches are associated with a specific instance of an Index Searcher—a specific view of an index that doesn't change during the lifetime of that searcher. As long as that Index Searcher is being used, any items in its cache will be valid and available for reuse. Caching in Solr differs from caching in many other applications in that cached Solr objects do not expire after a time interval; instead, they remain valid for the lifetime of the Index Searcher.

When a new searcher is opened, the current searcher continues servicing requests while the new one auto-warms its cache. The new searcher uses the current searcher's cache to pre-populate its own. When the new searcher is ready, it is registered as the current searcher and begins handling all new search requests. The old searcher will be closed once it has finished servicing all its requests.

In Solr 3.4, there are two cache implementations: `solr.search.LRUCache` and `solr.search.FastLRUCache`.

The acronym LRU stands for Least Recently Used. When an LRU cache fills up, the entry with the oldest last-accessed timestamp is evicted to make room for the new entry. The net effect is that entries that are accessed frequently tend to stay in the cache, while those that are not accessed frequently tend to drop out and will be re-fetched from the index if needed again.

The `FastLRUCache`, which was introduced in Solr 1.4, is designed to be lock-free, so it is well suited for caches which are hit several times in a request.

The Statistics page in the Solr Admin Web interface will display information about the performance of all the active caches. This information can help you fine-tune the sizes of the various caches appropriately for your particular application. When a Searcher terminates, a summary of its cache usage is also written to the log.

There are three predefined types of caches you can configure.

filterCache

This cache is used by `SolrIndexSearcher` for filters (DocSets) for unordered sets of all documents that match a query. The numeric attributes control the number of entries in the cache.

Solr uses the `filterCache` to cache results of queries that use the `fq` search parameter. Subsequent queries using the same parameter setting result in cache hits and rapid returns of results. See [Searching](#) for a detailed discussion of the `fq` parameter.

Solr also makes this cache for faceting when the configuration parameter `facet.method` is set to `fc`. For a discussion of faceting, see [Searching](#).

```
<filterCache
  class="solr.LRUCache"
  size="512"
    initialSize="512"
  autowarmCount="128" />
```

queryResultCache

This cache holds the results of previous searches: ordered lists of document IDs (DocList) based on a query, a sort, and the range of documents requested.

```
<queryResultCache
  class="solr.LRUCache"
  size="512"
    initialSize="512"
  autowarmCount="128" />
```

documentCache

This cache holds Lucene Document objects (the stored fields for each document). Since Lucene internal document IDs are transient, this cache is not auto-warmed.

```
<documentCache class="solr.LRUCache"
  size="512"
    initialSize="512"
  autowarmCount="0" />
```

User Defined Caches

You can also define named caches for your own application code to use. You can locate and use your cache object by name by calling the `SolrIndexSearcher` methods `getCache()`, `cacheLookup()` and `cacheInsert()`. If you want auto-warming of your cache, include a `regenerator` attribute with the fully qualified name of a class that implements `solr.search.CacheRegenerator`.

```
<cache name="myUserCache"
  class="solr.LRUCache"
  size="4096"
    initialSize="1024"
  autowarmCount="1024"
    regenerator="org.mycompany.mypackage.MyRegenerator" />
```

maxBooleanClauses

This sets the maximum number of clauses allowed in a boolean query. This can affect range or prefix queries that expand to a query with a large number of boolean terms. If this limit is exceeded, an exception is thrown.

```
<maxBooleanClauses>
1024
</maxBooleanClauses>
```

enableLazyFieldLoading

If this parameter is set to true, then fields that are not directly requested will be loaded lazily as needed. This can boost performance if the most common queries only need a small subset of fields, especially if infrequently accessed fields are large in size.

```
<enableLazyFieldLoading>
true
</enableLazyFieldLoading>
```

useColdSearcher

This setting controls whether search requests for which there is not a currently registered searcher should wait for a new searcher to warm up (false) or proceed immediately (true). When set to "false", requests will block until the searcher has warmed its caches.

```
<useColdSearcher>
false
</useColdSearcher>
```

maxWarmingSearchers

This parameter sets the maximum number of searchers that may be warming up in the background at any given time. Exceeding this limit will raise an error. For read-only slaves, a value of two is reasonable. Masters should probably be set a little higher.

```
<maxWarmingSearchers>
2
</maxWarmingSearchers>
```

HTTP RequestDispatcher Settings

The `requestDispatcher` element of `solrconfig.xml` controls the way the Solr servlet's `RequestDispatcher` implementation responds to HTTP requests.

handleSelect Attribute

The first configurable item is the `handleSelect` attribute on the `<requestDispatcher>` element itself. This attribute can be set to one of two values, either `"true"` or `"false"`. A value of `"true"` (the default) indicates that error handling should be consistent for `/select` and `/update` URLs. The value `"false"` indicates that error formatting should be compatible with Solr 1.1.

```
<requestDispatcher handleSelect="true" >
  ...
</requestDispatcher>
```

requestParsers Element

The `<requestParsers>` sub-element controls values related to parsing requests. This is an empty XML element that doesn't have any content, only attributes. The attribute `enableRemoteStreaming` controls whether remote streaming of content is allowed. If set to `false` (the default), streaming will not be allowed. Setting it to `true` lets you specify the location of content to be streamed using `stream.file` or `stream.url` parameters.

If you enable remote streaming, be sure that you have authentication enabled. Otherwise, someone could potentially gain access to your content by accessing arbitrary URLs. It's also a good idea to place Solr behind a firewall to prevent it being accessed from untrusted clients.

The attribute `multipartUploadLimitInKB` sets an upper limit on the size of a document that may be submitted in a multi-part HTTP POST request. The value specified is multiplied by 1024 to determine the size in bytes.

```
<requestDispatcher handleSelect="true">
  <requestParsers
    enableRemoteStreaming="false"
    multipartUploadLimitInKB="2048" />
</requestDispatcher>
```

httpCaching Element

The `<httpCaching>` element controls HTTP cache control headers. Do not confuse these settings with Solr's internal cache configuration. This element controls caching of HTTP responses as defined by the W3C HTTP specifications.

This element allows for three attributes and one sub-element. The attributes of the `<httpCaching>` element control whether a 304 response to a GET request is allowed, and if so, what sort of response it should be. When an HTTP client application issues a GET, it may optionally specify that a 304 response is acceptable if the resource has not been modified since the last time it was fetched.

Parameter	Description
never304	If present with the value <code>true</code> , then a GET request will never respond with a 304 code, even if the requested resource has not been modified. When this attribute is set to <code>true</code> , the following two attributes are ignored. Setting this to <code>true</code> is handy for development, as the 304 response can be confusing when tinkering with Solr responses through a web browser or other client that supports cache headers.
lastModFrom	This attribute may be set to either <code>openTime</code> (the default) or <code>dirLastMod</code> . The value <code>openTime</code> indicates that last modification times, as compared to the If-Modified-Since header sent by the client, should be calculated relative to the time the Searcher started. Use <code>dirLastMod</code> if you want times to exactly correspond to when the index was last updated on disk.
etagSeed	This value of this attribute is sent as the value of the <code>ETag</code> header. Changing this value can be helpful to force clients to re-fetch content even when the indexes have not changed—for example, when you've made some changes to the configuration.

```
<httpCaching never304="false"
  lastModFrom="openTime"
  etagSeed="Solr">
  <cacheControl>max-age=30, public
</cacheControl>
</httpCaching>
```

The cacheControl Element

In addition to these attributes, `<httpCaching>` accepts one child element: `<cacheControl>`. The content of this element will be sent as the value of the Cache-Control header on HTTP responses. This header is used to modify the default caching behavior of the requesting client. The possible values for the Cache-Control header are defined by the HTTP 1.1 specification in [Section 14.9](#).

Setting the max-age field controls how long a client may re-use a cached response before requesting it again from the server. This time interval should be set according to how often you update your index and whether or not it is acceptable for your application to use content that is somewhat out of date. Setting must-revalidate will tell the client to validate with the server that its cached copy is still good before re-using it. This will ensure that the most timely result is used, while avoiding a second fetch of the content if it isn't needed, at the cost of a request to the server to do the check.

Configuring solr.xml

Use the `solr.xml` to configure your Solr core, or to configure multiple cores. You can find `solr.xml` in your Solr Home directory. The default `solr.xml` file looks like this:

```
<solr persistent="false">
  <cores adminPath="/admin/cores" defaultCoreName="collection1">
    <core name="collection1" instanceDir="." />
  </cores>
</solr>
```

For more information about core configuration and `solr.xml`, see <http://wiki.apache.org/solr/CoreAdmin>.

Using Multiple SolrCores

It is possible to segment Solr into multiple cores, each with its own configuration and indices. Cores may be dedicated to a single application or to very different ones, but all are administered through a common administration interface. You can create new Solr cores on the fly, shutdown cores, even replace one running core with another, all without ever stopping or restarting your servlet container.

Solr cores are configured by placing a file named `solr.xml` in your `solr.home` directory. A typical `solr.xml` looks like this:

```
<solr persistent="true" sharedLib="lib">
  <cores adminPath="/admin/cores">
    <core name="core0" instanceDir="core0dir"/>
    <core name="core1" instanceDir="core1dir"/>
  </cores>
</solr>
```

This sets up two Solr cores, named "core0" and "core1" and names the directories (relative to the Solr installation path) which will store the configuration and data subdirectories.

 You can run Solr without configuring any cores.

The <solr> Element

There are two attributes that you can specify on `<solr>`, which is the root element of `solr.xml`.

Attribute	Description
persistent	Indicates that changes made through the API or admin UI should be saved back to this <code>solr.xml</code> . If not <code>true</code> , any runtime changes will be lost on the next Solr restart. The servlet container running Solr must have sufficient permissions to replace <code>solr.xml</code> (file delete and create), or errors will result. Any comments in <code>solr.xml</code> are not preserved when the file is updated.
sharedLib	Specifies the path to a common library directory that will be shared across all cores. Any JAR files in this directory will be added to the search path for Solr plugins. This path is relative to the top-level container's Solr Home.

 If you set the `persistent` attribute to `true`, be sure that the Web server has permission to replace the file. If the permissions are set incorrectly, the server will generate 500 errors and throw `IOExceptions`. Also, note that any comments in the `solr.xml` file will be lost when the file is overwritten.

The <cores> Element

The `<cores>` element, which contains definitions for each Solr core, is a child of `<solr>` and accepts three attributes of its own.

Attribute	Description
adminPath	This is the relative URL path to access the SolrCore administration pages. For example, a value of <code>/admin/cores</code> means that you can access the <code>CoreAdminHandler</code> with a URL that looks like this: http://localhost:8983/solr/admin/cores If this attribute is not present, then SolrCore administration will not be possible.
shareSchema	This attribute, when set to <code>true</code> , ensures that the multiple cores pointing to the same <code>schema.xml</code> will be referring to the same <code>IndexSchema</code> Object. Sharing the <code>IndexSchema</code> Object makes loading the core faster. If you use this feature, make sure that no core-specific property is used in your <code>schema.xml</code> .
adminHandler	If used, this attribute should be set to the <code>FQN</code> (Fully qualified name) of a class that inherits from <code>CoreAdminHandler</code> . For example, <code>adminHandler="com.myorg.MyAdminHandler"</code> would configure the custom admin handler (<code>MyAdminHandler</code>) to handle admin requests. If this attribute isn't set, Solr uses the default admin handler, <code>org.apache.solr.handler.admin.CoreAdminHandler</code> .

For a use case of the `adminHandler` attribute, suppose we wanted to get statistics from different cores in a Solr instance. First, we could define a new action called `mystat` that could be accessed from the client as below.

```
http://localhost:8983/solr/admin/cores?action=MYSTAT
```

Then, we would define the implementation of the MYSTAT action like so:

```
import org.apache.solr.handler.admin.CoreAdminHandler ;
class MyAdminHandler extends CoreAdminHandler {

    /**
     * @return true, if the changes need to be persisted by the CoreContainer. (Use only
     if solr.xml would be changed because of this action.)
     *         false, otherwise. (Use this if unsure or having a read-only access to the
     CoreContainer like collecting statistics)
     */
    protected boolean handleCustomAction(SolrQueryRequest req, SolrQueryResponse rsp) {
        CoreContainer container = super.getCoreContainer();
        *SolrCore* mycore1 = container.getCore("core1");
        *SolrCore* mycore2 = container.getCore("core2");
        SolrParams params = req.getParams();
        String a = params.get( CoreAdminParams.ACTION );
        if (a.toLowerCase().equals("mystat")) {
            // TODO: populate 'rsp' as necessary.
        }
    }
}
```

There are other methods in [CoreAdminHandler](#) that could be used to override default actions, but for most of the common cases they would not be necessary.

The <core> Element

There is one `<core>` element for each `SolrCore` you define. They are children of the `<cores>` element and each one accepts six attributes.

Attribute	Description
name	The name of the <code>SolrCore</code> . You'll use this name to reference the <code>SolrCore</code> when running commands with the <code>CoreAdminHandler</code> .
instanceDir	This relative path defines the Solr Home for the core.
config	The configuration file name for a given core. The default is <code>solrconfig.xml</code> .

schema	The schema file name for a given core. The default is <code>schema.xml</code>
dataDir	This relative path defines the Solr Home for the core.
properties	The name of the properties file for this core. The value can be an absolute pathname or a path relative to the value of <code>instanceDir</code> .

Properties in solr.xml

You can define properties in `solr.xml` that you may then reference in `solrconfig.xml` and `schema.xml`. Properties are name/value pairs. The scope of a property depends on which element it occurs within.

```
<solr persistent="true" sharedLib="lib">
  <property name="productname" value="Acme Online"/>
  <cores adminPath="/admin/cores">
    <core name="core0" instanceDir="core0">
      <property name="dataDir" value="/data/core0"/></core>
    <core name="core1" instanceDir="core1"/>
  </cores>
</solr>
```

If a property is declared under `<solr>` but outside a `<core>` element, then it will have container scope and will be visible to all cores. In the example above, `productname` is such a property.

If a property declaration occurs within a `<core>` element, then its scope is limited to that core and it will not be visible to other cores. A property at core scope will override one of the same name declared at container scope.

In addition to any properties you declare at core scope, there are several properties that Solr defines automatically for each core. These properties are described in the table below:

Property	Description
<code>solr.core.name</code>	The core's name, as defined by the "name" attribute.
<code>solr.core.instanceDir</code>	The core's instance directory under which that its <code>conf/</code> and <code>data/</code> directories are located, derived from the core's <code>instanceDir</code> attribute.
<code>solr.core.dataDir</code>	The core's data directory, <code>\${solr.core.instanceDir}/data</code> by default.
<code>solr.core.configName</code>	The name of the core's configuration file, <code>solrconfig.xml</code> by default.
<code>solr.core.schemaName</code>	The name of the core's schema file, <code>schema.xml</code> by default.

Any of the above properties can be referenced by name in `schema.xml` or `solrconfig.xml`.

When defining properties, you can assign a property a default value that will be used if another value isn't specified. For example:

```
// Without a default value, result will be empty if property not defined
```

```
${productname}
```

```
// With a default value
```

```
${productname:SearchCo MegaIndex}
```

CoreAdminHandler

The CoreAdminHandler is a special SolrRequestHandler that is used to manage Solr cores. Unlike normal SolrRequestHandlers, the CoreAdminHandler is not attached to a single core. Instead, it manages all the cores running in a single Solr instance. Only one CoreAdminHandler exists for each top-level Solr instance.

To use the CoreAdminHandler, make sure that the `adminPath` attribute is defined on the `<cores>` element; otherwise you will not be able to make HTTP requests to perform Solr core administration.

The CoreAdminHandler supports seven different actions that may be invoked on the `adminPath` URL. The action to perform is named by the HTTP request parameter "action", with arguments for a specific action being provided as additional parameters.

All action names are uppercase. The actions names are:

- [STATUS](#)
- [CREATE](#)
- [RELOAD](#)
- [RENAME](#)
- [ALIAS](#)
- [SWAP](#)
- [UNLOAD](#)

These actions are described in detail in the sections below.

STATUS

The `STATUS` action returns the status of all running Solr cores, or status for only the named core.

```
http://localhost:8983/solr/admin/cores?action=STATUS
```

```
http://localhost:8983/solr/admin/cores?action=STATUS&core=core0
```

The `STATUS` action accepts one optional parameter:

Parameter	Description
core	(Optional) The name of a core, as listed in the "name" attribute of a <code><core></code> element in <code>solr.xml</code> .

CREATE

The `CREATE` action creates a new core and registers it. If persistence is enabled (`persistent="true"` on the `<solr>` element), the updated configuration for this new core will be saved in `solr.xml`. If a Solr core with the given name already exists, it will continue to handle requests while the new core is initializing. When the new core is ready, it will take new requests and the old core will be unloaded.

```
http://localhost:8983/solr/admin/cores?action=CREATE
&name=coreX&instanceDir=path/to/dir
&config=config_file_name.xml&schema=schem_file_name.xml&dataDir=data
```

The `CREATE` accepts the two mandatory parameters, as well as three optional parameters.

Parameter	Description
name	The name of the new core. Same as "name" on the <code><core></code> element.
instanceDir	The directory where files for this SolrCore should be stored. Same as <code>instanceDir</code> on the <code><core></code> element.
config	(Optional) Name of the config file (<code>solrconfig.xml</code>) relative to <code>instanceDir</code> .
schema	(Optional) Name of the schema file (<code>schema.xml</code>) relative to <code>instanceDir</code> .
datadir	(Optional) Name of the data directory relative to <code>instanceDir</code> .

RELOAD

The `RELOAD` action loads a new core from the configuration of an existing, registered Solr core. While the new core is initializing, the existing one will continue to handle requests. When the new Solr core is ready, it takes over and the old core is unloaded.

This is useful when you've made changes to a Solr core's configuration on disk, such as adding new field definitions. Calling the `RELOAD` action lets you apply the new configuration without having to restart the Web container.

```
http://localhost:8983/solr/admin/cores?action=RELOAD&core=core0
```

The `RELOAD` action accepts a single parameter

Parameter	Description
core	The name of the core to be reloaded.

RENAME

The `RENAME` action changes the name of a Solr core.

```
http://localhost:8983/solr/admin/cores?action=RENAME
&core=core0&other=core5
```

The `RENAME` action requires the following two parameter:

Parameter	Description
core	The name of the Solr core to be renamed.
other	The new name for the Solr core. If the persistent attribute of <code><solr></code> is <code>true</code> , the new name will be written to <code>solr.xml</code> as the <code>name</code> attribute of the <code><core></code> attribute.

ALIAS

The `ALIAS` action establishes an additional name by which a SolrCore may be referenced. Subsequent actions may use the Solr core's original name or any of its aliases.

 This action is still considered experimental.

```
http://localhost:8983/solr/admin/cores?action=ALIAS&core=coreX&other=coreY
```

The `ALIAS` action requires two parameters:

Parameter	Description
core	The name or alias of an existing core.
other	The additional name by which this core should be known.

SWAP

`SWAP` atomically swaps the names used to access two existing Solr cores. This can be used to swap new content into production. The prior core remains available and can be swapped back, if necessary. Each core will be known by the name of the other, after the swap.

```
http://localhost:8983/solr/admin/cores?action=SWAP&core=core1&other=core0
```

The `SWAP` action requires two parameters, which are described in the table below.

Parameter	Description
core	The name of one of the cores to be swapped.
other	The name of one of the cores to be swapped.

UNLOAD

The `UNLOAD` action removes a core from Solr. Active requests will continue to be processed, but no new requests will be sent to the named core. If a core is registered under more than one name, only the given name is removed.

`http://localhost:8983/solr/admin/cores?action=UNLOAD&core=core0`

The `UNLOAD` action requires a parameter identifying the core to be removed.

Parameter	Description
core	The name of the core to be to be removed. If the persistent attribute of <code><solr></code> is set to <code>true</code> , the <code><core></code> element with this <code>name</code> attribute will be removed from <code>solr.xml</code> .

Solr Plugins

Solr allows you to load custom code to perform a variety of tasks within Solr, from custom Request Handlers to process your searches, to custom Analyzers and Token Filters for your text field. You can even load custom Field Types. These pieces of custom code are called plugins.

Not everyone will need to create plugins for their Solr instances - what's provided is usually enough for most applications. However, if there's something that you need, you may want to review the Solr Wiki documentation on plugins at [SolrPlugins](#).

JVM Settings

Configuring your JVM can be a complex topic. A full discussion is beyond the scope of this document. Luckily, most modern JVMs are quite good at making the best use of available resources with default settings. The following sections contain a few tips that may be helpful when the defaults are not optimal for your situation.

For more general information about improving Solr performance, see <https://wiki.apache.org/solr/SolrPerformanceFactors>.

Choosing Memory Heap Settings

The most important JVM configuration settings are those that determine the amount of memory it is allowed to allocate. There are two primary command-line options that set memory limits for the JVM. These are `-Xms`, which sets the initial size of the JVM's memory heap, and `-Xmx`, which sets the maximum size to which the heap is allowed to grow.

If your Solr application requires more heap space than you specify with the `-Xms` option, the heap will grow automatically. It's quite reasonable to not specify an initial size and let the heap grow as needed. The only downside is a somewhat slower startup time since the application will take longer to initialize. Setting the initial heap size higher than the default may avoid a series of heap expansions, which often results in objects being shuffled around within the heap, as the application spins up.

The maximum heap size, set with `-Xmx`, is more critical. If the memory heap grows to this size, object creation may begin to fail and throw `OutOfMemoryException`. Setting this limit too low can cause spurious errors in your application, but setting it too high can be detrimental as well.

It doesn't always cause an error when the heap reaches the maximum size. Before an error is raised, the JVM will first try to reclaim any available space that already exists in the heap. Only if all garbage collection attempts fail will your application see an exception. As long as the maximum is big enough, your app will run without error, but it may run more slowly if forced garbage collection kicks in frequently.

The larger the heap the longer it takes to do garbage collection. This can mean minor, random pauses or, in extreme cases, "freeze the world" pauses of a minute or more. As a practical matter, this can become a serious problem for heap sizes that exceed about two gigabytes, even if far more physical memory is available. On beefy hardware, you may get better results running multiple JVMs, rather than just one with a huge memory heap. Some specialized JVM implementations may have customized garbage collection algorithms which do better with large heaps. Also, Java 7 is anticipated to have a redesigned GC that should handle very large heaps efficiently. Consult your JVM vendor's documentation.

When setting the maximum heap size, be careful not to let the JVM consume all available physical memory. If the JVM process space grows too large, the operating system will start swapping it, which will severely impact performance. In addition, the operating system uses memory space not allocated to processes for file system cache and other purposes. This is especially important for I/O-intensive applications, like Lucene/Solr. The larger your indices, the more you will benefit from filesystem caching by the OS. It may require some experimentation to determine the optimal tradeoff between heap space for the JVM and memory space for the OS to use.

On systems with many CPUs/cores, it can also be beneficial to tune the layout of the heap and/or the behavior of the garbage collector. Adjusting the relative sizes of the generational pools in the heap can affect how often GC sweeps occur and whether they run concurrently. Configuring the various settings of how the garbage collector should behave can greatly reduce the overall performance impact when it does run. There is a lot of good information on this topic available on Sun's website. A good place to start is here: <http://java.sun.com/javase/technologies/hotspot/gc/>.

Use the Server HotSpot VM

If you're using Sun's JVM, be sure to add the `-server` command-line option when you start Solr. This tells the JVM that it should optimize for a long running, server process. If the Java runtime on your system is a JRE, rather than a full JDK distribution (including `javac` and other development tools), then it's possible that it may not support the `-server` JVM option. Test this by running `java -help` and look for `-server` as an available option in the displayed usage message.

Checking JVM Settings

A great way to see what JVM settings your server is using, along with other useful information, is to use the admin RequestHandler, `solr/admin/system`. This request handler will display a wealth of server statistics and settings.

You can also use any of the tools that are compatible with the Java Management Extensions (JMX). See the section *Using JMX with Solr* in [Managing Solr](#) for more information.

Managing Solr

This section describes how to run Solr and how to look at Solr when it is running. It contains the following sections:

[Running Solr on Jetty](#): Describes how to run Solr in the Jetty web application container. The Solr example included in this distribution runs in a Jetty web application container.

[Running Solr on Tomcat](#): Describes how to run Solr in the Tomcat web application container.

[Configuring Logging](#): Describes how to configure logging for Solr.

[Backing Up](#): Describes backup strategies for your Solr indexes.

[Using JMX with Solr](#): Describes how to use Java Management Extensions with Solr.

For information on running Solr in a variety of Java application containers, see the [basic installation instructions](#) on the Solr wiki.

Running Solr on Tomcat

Solr comes with an example schema and scripts for running on [Jetty](#). The next section describes some of the details of how things work "under the hood," and covers running multiple Solr instances and deploying Solr using the Tomcat application manager.

For more information about running Solr on Tomcat, see the [basic installation instructions](#) and the [Solr Tomcat](#) page on the Solr wiki.

How Solr Works with Tomcat

The two basic steps for running Solr in any Web application container are as follows:

1. Make the Solr classes available to the container. In many cases, the Solr Web application archive (WAR) file can be placed into a special directory of the application container. In the case of Tomcat, you need to place the Solr WAR file in Tomcat's `webapps` directory. If you installed Tomcat with Solr, take a look in `tomcat/webapps`: you'll see the `solr.war` file is already there.
2. Point Solr to the Solr home directory that contains `conf/solrconfig.xml` and `conf/schema.xml`. There are a few ways to get this done. One of the best is to define the `solr.solr.home` Java system property. With Tomcat, the best way to do this is via a shell environment variable, `JAVA_OPTS`. Tomcat puts the value of this variable on the command line upon startup. Here is an example:

```
export JAVA_OPTS="-Dsolr.solr.home=/Users/jonathan/Desktop/solr"
```

Port 8983 is the default Solr listening port. If you are using Tomcat and wish to change this port, edit the file `tomcat/conf/server.xml` in the Solr distribution. You'll find the port in this part of the file:

```
<Connector port="8983" protocol="HTTP/1.1" connectionTimeout="20000"
redirectPort="8443" />
```

Modify the port number as desired and restart Tomcat if it is already running.

Modifying the port number will leave some of the samples and help file links pointing to the default port. It is out of the scope of this reference guide to provide full details of how to change all of the examples and other resources to the new port.

Running Multiple Solr Instances

The standard way to deploy multiple Solr index instances in a single Web application is to use the multicore API described in [Using Multiple SolrCores](#).

An alternative approach, which provides more code isolation, uses Tomcat context fragments. A context fragment is a file that contains a single `<context>` element and any subelements required for your application. The file omits all other XML elements.

Each context fragment specifies where to find the Solr WAR and the path to the solr home directory. The name of the context fragment file determines the URL used to access that instance of Solr. For example, a context fragment named `harvey.xml` would deploy Solr to be accessed at `http://localhost:8983/harvey`.

In Tomcat's `conf/Catalina/localhost` directory, store one context fragment per instance of Solr. If the `conf/Catalina/localhost` directory doesn't exist, go ahead and create it.

Using Tomcat context fragments, you could run multiple instances of Solr on the same server, each with its own schema and configuration. For full details and examples of context fragments, take a look at the Solr Wiki: <http://wiki.apache.org/solr/SolrTomcat>.

Here are examples of context fragments which would set up two Solr instances, each with its own `solr.home`:

```
<Context docBase="/some/path/solr.war" debug="0" crossContext="true" >
  <Environment name="solr/home" type="java.lang.String" value="/some/path/solr1home"
  override="true" />
</Context>
<Context docBase="/some/path/solr.war" debug="0" crossContext="true" >
  <Environment name="solr/home" type="java.lang.String"
  value="/some/path/solr2home" override="true" />
</Context>
```

Deploying Solr with the Tomcat Manager

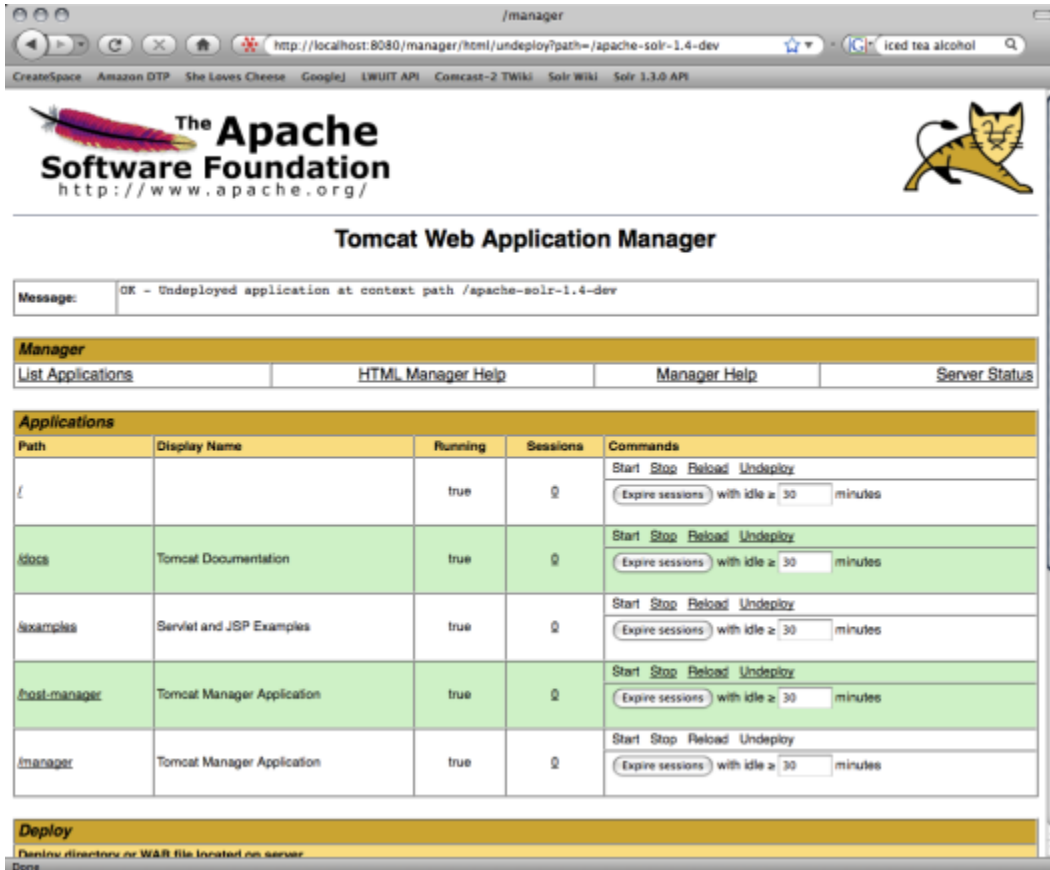

If your instance of Tomcat is running the Tomcat Web Application Manager, you can use its browser interface to deploy Solr.

Just as before, you have to tell Solr where to find the solr home directory. You can do this by setting `JAVA_OPTS` before starting Tomcat.

Once Tomcat is running, navigate to the Web application manager, probably available at a URL like this:

```
http://localhost:8983/manager/html
```

You'll see the main screen of the manager.

To add Solr, scroll down to the **Deploy** section, specifically **WAR file to deploy**. Click **Browse...** and find the Solr WAR file, usually something like `dist/apache-solr-3.4.0.war` within your Solr installation. Click **Deploy**. Tomcat will load the WAR file and start running it. Click the link in the application path column of the manager to see Solr. You won't see much, just a welcome screen, but it contains a link for the Admin Console.

Tomcat's manager screen, in its application list, has links so you can stop, start, reload, or undeploy the Solr application.

Running Solr on Jetty

Solr comes with an example schema and scripts for running on [Jetty](#), along with a working installation, in the `/example` directory. Jetty works well for small installations, but may not be appropriate for more heavy-duty use. For more robust Solr applications, we recommend [JettyPlus](#)

For more information about the Jetty example installation, see the [Solr Tutorial](#) and the [basic installation instructions](#) on the Solr wiki.

For detailed information about running Solr on Jetty or JettyPlus, see <http://wiki.apache.org/solr/SolrJetty>.

Changing the Solr Listening Port

Port 8983 is the default port for Solr. If you are using Jetty and wish to change the port number, edit the file `jetty/etc/jetty.xml` in the Solr distribution. You'll find the port in this part of the file:

```
<New class="org.mortbay.jetty.bio.SocketConnector">
  <Set name="port"><SystemProperty name="jetty.port"
default="8983"/></Set>
  <Set name="maxIdleTime">50000</Set>
  <Set name="lowResourceMaxIdleTime">1500</Set>
</New>
```

Modify the port number as desired and restart Jetty if it is already running.

Modifying the port number will leave some of the samples and help file links pointing to the default port. It is out of the scope of this reference guide to provide full details of how to change all of the examples and other resources to the new port.

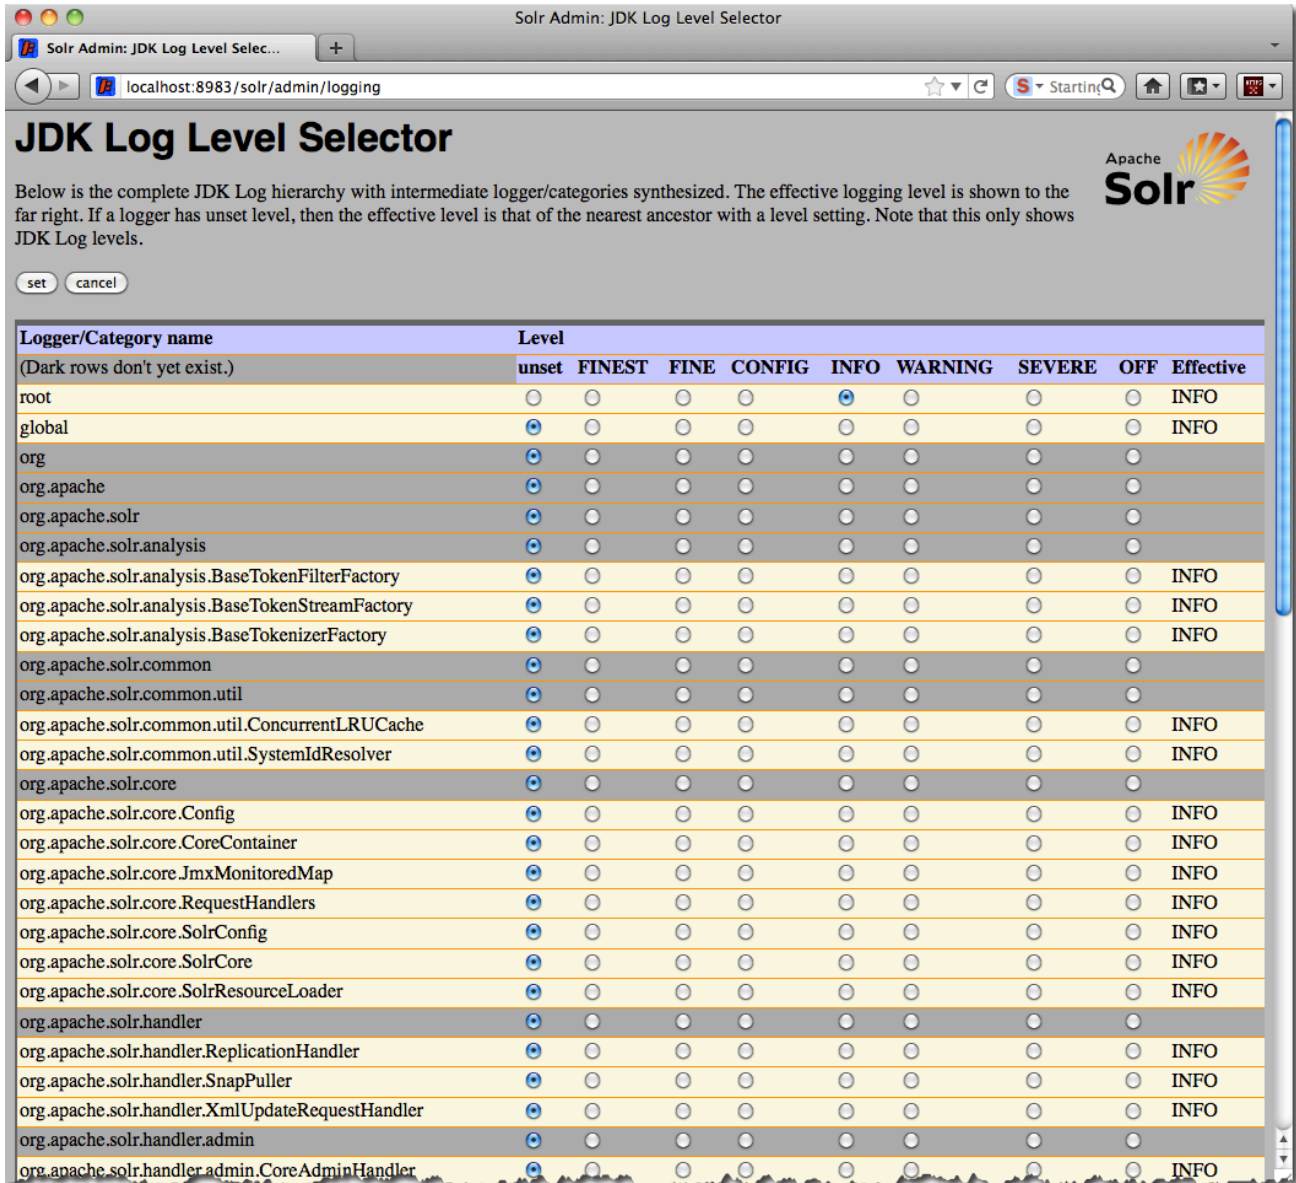

Configuring Logging

Logging is the practice of writing informative messages somewhere. System administrators or developers can read logs to learn information about a system. If an application dies unexpectedly, the key to its demise might be written in a log somewhere. A canny developer can examine a log to understand what went wrong, much like a detective can examine the scene of a crime to find out what happened.

Solr uses the SLF4J Logging API (<http://www.slf4j.org>). If you want to see the log output in Tomcat, look in `solr/tomcat/logs`. You'll find a file named something like `catalina.2011-05-01.log`, except with the current date.

Temporary Logging Settings

You can control the amount of logging output in Solr by using the Admin Web interface. Select the **LOGGING** link. Note that this page only lets you change settings in the running system and is not saved for the next run. (For more information about the Admin Web interface, see [Using the Solr Administration User Interface](#).)

The JDK Log Level Selector screen.

This part of the Admin Web interface allows you to set the logging level for many different log categories. Fortunately, any categories that are **unset** will have the logging level of its parent. This makes it possible to change many categories at once by adjusting the logging level of their parent.

Permanent Logging Settings

Making permanent changes to the JDK Logging API configuration is a matter of creating or editing a properties file.

Tomcat Logging Settings

Tomcat offers a choice between settings for all applications or settings specifically for the Solr application.

To change logging settings for Solr only, edit

`tomcat/webapps/solr/WEB-INF/classes/logging.properties`. You will need to create the classes directory and the `logging.properties` file. You can set levels from `FINEST` to `SEVERE` for a class or an entire package. Here are a couple of examples:

```
org.apache.commons.digester.Digester.level = FINEST
org.apache.solr.level = WARNING
```

Alternately, if you wish to change Tomcat's JDK Logging API settings for every application in this instance of Tomcat, edit `tomcat/conf/logging.properties`.

See the documentation for the SLF4J Logging API for more information:

<http://slf4j.org/docs.html>

<http://java.sun.com/javase/6/docs/technotes/guides/logging/index.html>

Jetty Logging Settings

To change settings for the SLF4J Logging API in Jetty, you need to create a settings file and tell Jetty where to find it.

Begin by creating a file `jetty/logging.properties`. Use the example lines above as a guide.

To tell Jetty how to find the file, edit `start.sh`. Find the line which launches Jetty, which looks something like this, except it will have an absolute path to `start.jar`:

```
java -DSTOP.PORT=8079 -DSTOP.KEY=secret -jar start.jar

#Add the location of the logging properties file like this:

java -Djava.util.logging.config.file=logging.properties
-DSTOP.PORT=8079 -DSTOP.KEY=secret -jar start.jar
```

The next time you launch Jetty, it will use the settings in the file.

Backing Up

If you are worried about data loss, and of course you *should* be, you need a way to back up your Solr indexes so that you can recover quickly in case of catastrophic failure.

Making Backups with the Solr Replication Handler

The easiest way to make back-ups in Solr is to take advantage of the Replication Handler, which is described in detail in [Index Replication](#). The Replication Handler's primary purpose is to replicate an index on slave servers for load-balancing, but the Replication Handler can be used to make a back-up copy of a server's index, even if no slave servers are in operation.

Once you've configured the Replication Handler in `solrconfig.xml`, you can trigger a back-up with an HTTP command like this:

```
http:// master_host /solr/replication?command=backup
```

For details on configuring the Replication Handler, see [Scaling and Distribution](#).

Backup Scripts from Earlier Solr Releases

Solr also provides shell scripts in the `bin` directory that make copies of the indexes. However, these scripts only work with a Linux-style shell, and not everybody in the world runs Linux.

The scripts themselves are relatively simple. Look in the `bin` directory of your Solr home directory, for example `example/solr/bin`. In particular, `backup.sh` makes a copy of Solr's index directory and gives it a name based on the current date.

This scripts include the following:

Script Name	Description
abc	Atomic Backup post-Commit tells the Solr server to perform a commit. A snapshot of the index directory is made after the commit if the Solr server is configured to do so (by enabling the postCommit event listener in <code>solr/conf/solrconfig.xml</code>). A backup of the most recent snapshot directory is then made if the commit is successful. Backup directories are named <code>backup.yyyymmddHHMMSS</code> where <code>yyymmddHHMMSS</code> is the timestamp of when the snapshot was taken.

abo	Atomic Backup post-Optimize tells the Solr server to perform an optimize. A snapshot of the index directory is made after the optimize if the Solr server is configured to do so (by enabling the postCommit or postOptimize event listener in <code>solr/conf/solrconfig.xml</code>). A backup of the most recent snapshot directory is then made if the optimize is successful. Backup directories are named <code>backup.yyyyymmddHHMMSS</code> where <code>yyyymmddHHMMSS</code> is the timestamp of when the snapshot was taken.
backup	Backs up the index directory using hard links. Backup directories are named <code>backup.yyyyymmddHHMMSS</code> where <code>yyyymmddHHMMSS</code> is the timestamp of when the backup was taken.
backupcleaner	Runs as a cron job to remove backups more than a configurable number of days old or all backups except for the most recent n number of backups. Also can be run manually.

For more details about backup scripts, see the Solr Wiki page <http://wiki.apache.org/solr/SolrOperationsTools>.

Using JMX with Solr

Java Management Extensions (JMX) is a technology that makes it possible for complex systems to be controlled by tools without the systems and tools having any previous knowledge of each other. In essence, it is a standard interface by which complex systems can be viewed and manipulated.

Solr, like any other good citizen of the Java universe, can be controlled via a JMX interface. You can enable JMX support by adding lines to `solrconfig.xml`. You can use a JMX client, like `jconsole`, to connect with Solr. Check out the Wiki page <http://wiki.apache.org/solr/SolrJmx> for more information. You may also find the following overview of JMX to be useful: <http://java.sun.com/j2se/1.5.0/docs/guide/management/agent.html>.

Scaling and Distribution

This section describes how to set up distribution and replication in Solr. It covers the following topics:

[Introduction to Scaling and Distribution](#): Conceptual information about distribution and replication in Solr.

[Distributed Search with Index Sharding](#): Detailed information about implementing distributed searching in Solr.

[Index Replication](#): Detailed information about replicating your Solr indexes.

[Combining Distribution and Replication](#): Detailed information about replicating shards in a distributed index.

[Merging Indexes](#): Information about combining separate indexes in Solr.

Introduction to Scaling and Distribution

Both Lucene and Solr were designed to scale to support large implementations with minimal custom coding. This section covers:

- [distributing](#) an index across multiple servers
- [replicating](#) an index on multiple servers
- [merging indexes](#)

What Problem Does Distribution Solve?

If searches are taking too long or the index is approaching the physical limitations of its machine, you should consider distributing the index across two or more Solr servers.

To distribute an index, you divide the index into partitions called shards, each of which runs on a separate machine. Solr then partitions searches into sub-searches, which run on the individual shards, reporting results collectively. The architectural details underlying index sharding are invisible to end users, who simply experience faster performance on queries against very large indexes.

What Problem Does Replication Solve?

Replicating an index is useful when:

- You have a large search volume which one machine cannot handle, so you need to distribute searches across multiple read-only copies of the index.
- There is a high volume/high rate of indexing which consumes machine resources and reduces search performance on the indexing machine, so you need to separate indexing and searching.
- You want to make a backup of the index (see [Backing Up](#)).

Distributed Search with Index Sharding

When an index becomes too large to fit on a single system, or when a query takes too long to execute, an index can be split into multiple shards, and Solr can query and merge results across those shards. A single shard receives the query, distributes the query to other shards, and integrates the results. You can find additional information about distributed search on the Solr wiki: <http://wiki.apache.org/solr/DistributedSearch>.

The figure below compares a single server to a distributed configuration with two shards.

- i If single queries are currently fast enough and one simply wishes to expand the capacity (queries/sec) of the search system, then standard index replication (replicating the entire index on multiple servers) should be used instead of index sharding.

Distributing Documents across Shards

It's up to you to get all your documents indexed on each shard of your server farm. Solr does not include out-of-the-box support for distributed indexing, but your method can be as simple as a round robin technique. Just index each document to the next server in the circle. (For more information about indexing, see [Indexing and Basic Data Operations](#).)

A simple hashing system would also work. The following should serve as an adequate hashing function.

```
uniqueId.hashCode() % numServers
```

One advantage of this approach is that it's easy to know where a document is if you need to update it or delete. In contrast, if you're moving documents around in a round-robin fashion, you may not know where a document actually is.

Solr does not calculate universal term/doc frequencies. For most large-scale implementations, it's not likely to matter that Solr calculates TD/IDF at the shard level. However, if your collection is heavily skewed in its distribution across servers, you may find misleading relevancy results in your searches. In general, it's probably best to randomly distribute documents to your shards.

Executing Distributed Searches with the `shards` Parameter

If a query request includes the `shards` parameter, the Solr server distributes the request across all the shards listed as arguments to the parameter. The `shards` parameter uses this syntax:

```
host : port / base_url [, host : port / base_url ]*
```

For example, the `shards` parameter below causes the search to be distributed across two Solr servers: **solr1** and **solr2**, both of which are running on port 8983:

```
http://localhost:8983/solr/select?
```

```
shards=solr1:8983/solr,solr2:8983/solr&indent=true&q=ipod+solr
```

Rather than require users to include the `shards` parameter explicitly, it's usually preferred to configure this parameter as a default in the RequestHandler section of `solrconfig.xml`.

Do not add the `shards` parameter to the standard requestHandler; otherwise, search queries may enter an infinite loop. Instead, define a new requestHandler that uses the `shards` parameter, and pass distributed search requests to that handler.

Currently, only query requests are distributed. This includes requests to the standard request handler (and subclasses such as the DisMax RequestHandler), and any other handler (`org.apache.solr.handler.component.searchHandler`) using standard components that support distributed search.

The following components support distributed search:

- The **Query** component, which returns documents matching a query
- The **Facet** component, which processes `facet.query` and `facet.field` requests where facets are sorted by count (the default).
- The **Highlighting** component, which enables Solr to include "highlighted" matches in field values.
- The **Stats** component, which returns simple statistics for numeric fields within the DocSet.
- The **Debug** component, which helps with debugging.

Limitations to Distributed Search

Distributed searching in Solr has the following following limitations:

- Each document indexed must have a unique key.
- If Solr discovers duplicate document IDs, Solr selects the first document and discards subsequent ones.
- Inverse-document frequency (IDF) calculations cannot be distributed.
- Distributed searching does not support the QueryElevationComponent, which configures the top results for a given query regardless of Lucene's scoring. For more information, see <http://wiki.apache.org/solr/QueryElevationComponent>.
- The index for distributed searching may become out of date; for example, a document that once matched a query and was subsequently changed may no longer match the query but will still be retrieved.
- Distributed searching supports only sorted-field faceting, not date faceting
- The number of shards is limited by number of characters allowed for GET method's URI; most Web servers generally support at least 4000 characters, but many servers limit URI length to reduce their vulnerability to Denial of Service (DoS) attacks.
- TF/IDF computations are per shard. This may not matter if content is well (randomly) distributed.

Avoiding Distributed Deadlock

Each shard may also serve top-level query requests and then make sub-requests to all of the other shards. In this configuration, care should be taken to ensure that the max number of threads serving HTTP requests in the servlet container is greater than the possible number of requests from both top-level clients and other shards. If this is not the case, the configuration may result in a distributed deadlock.

Here's how a deadlock might occur. Consider the simplest case of two shards, each with just a single thread to service HTTP requests. Both threads could receive a top-level request concurrently, and make sub-requests to each other. Because there are no more remaining threads to service requests, the servlet containers will block the incoming requests until the other pending requests are finished, but they won't finish since they are waiting for the sub-requests. By ensuring that the servlets are configured to handle a sufficient number of threads, you can avoid deadlock situations like this.

Testing Index Sharding on Two Local Servers

For simple functionality testing, it's easiest to just set up two local Solr servers on different ports. (In a production environment, of course, these servers would be deployed on separate machines.)

```
#make a copy of the solr example directory

cd solr

cp -r example example7574

#change the port number

perl -pi -e s/8983/7574/g example7574/etc/jetty.xml example7574/exampledocs/post.sh

#in window 1, start up the server on port 8983

cd examplejava -server -jar start.jar

#in window 2, start up the server on port 7574

cd example7574java -server -jar start.jar

#in window 3, index some example documents to each server

cd example/exampledocs./post.sh \[a-m\]\*.xmlcd ../../example7574/exampledocs./post.sh
\[n-z\]\*.xml

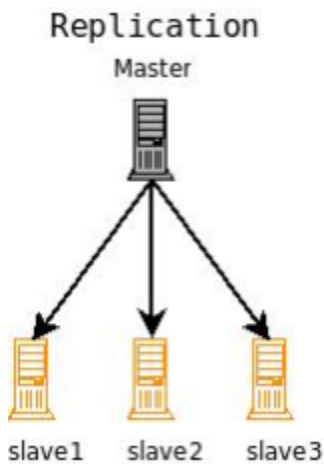

#now do a distributed search across both servers with your browser or curl

curl
'http://localhost:8983/solr/select?shards=localhost:8983/solr,localhost:7574/solr&indent=1'
```

Index Replication

Index Replication distributes complete copies of a master index to one or more slave servers. The master server continues to manage updates to the index. All querying is handled by the slaves. This division of labor enables Solr to scale to provide adequate responsiveness to queries against large search volumes.

The figure below shows a Solr configuration using index replication. The master server's index is replicated on the slaves.

A Solr index can be replicated across multiple slave servers, which then process requests.

Topics covered in this section:

- [Index Replication in Solr 3.4](#)
- [Replication Terminology](#)
- [Configuring the Replication RequestHandler on a Master Server](#)
- [Index Replication using ssh and rsync](#)
- [The Snapshot and Distribution Process](#)
- [Snapshot Directories](#)

- [Solr Distribution-related Cron Jobs](#)
- [Commit and Optimization](#)
- [Distribution and Optimization](#)
- [Performance Tuning for Script-based Replication](#)

Index Replication in Solr 3.4

Solr includes a Java implementation of index replication that works over HTTP.

For information on the `ssh/rsync` based replication, see [Index Replication using ssh and rsync](#).

The Java-based implementation of index replication offers these benefits:

- Replication without requiring external scripts
- The configuration affecting replication is controlled by a single file, `solrconfig.xml`
- Supports the replication of configuration files as well as index files
- Works across platforms with same configuration
- No reliance on OS-dependent hard links
- Tightly integrated with Solr; an admin page offers fine-grained control of each aspect of replication
- The Java-based replication feature is implemented as a RequestHandler. Configuring replication is therefore similar to any normal RequestHandler.

Replication Terminology

The table below defines the key terms associated with Solr replication.

Term	Definition
Collection	A Lucene collection is a directory of files. These files make up the indexed and returnable data of a Solr search repository.
Distribution	The copying of a collection from the master server to all slaves. The distribution process takes advantage of Lucene's index file structure.
Inserts and Deletes	As inserts and deletes occur in the collection, the directory remains unchanged. Documents are always inserted into newly created files. Documents that are deleted are not removed from the files. They are flagged in the file, <code>deletable</code> , and are not removed from the files until the collection is optimized.
Master and Slave	The Solr distribution model uses the master/slave model. The master is the service which receives all updates initially and keeps everything organized. Solr uses a single update master server coupled with multiple query slave servers. All changes (such as inserts, updates, deletes, etc.) are made against the single master server. Changes made on the master are distributed to all the slave servers which service all query requests from the clients.
Update	An update is a single change request against a single Solr instance. It may be a request to delete a document, add a new document, change a document, delete all documents matching a query, etc. Updates are handled synchronously within an individual Solr instance.

Optimization	A process that compacts the index and merges segments in order to improve query performance. New secondary segment(s) are created to contain documents inserted into the collection after it has been optimized. A Lucene collection must be optimized periodically to maintain satisfactory query performance. Optimization is run on the master server only. An optimized index will give you a performance gain at query time of at least 10%. This gain may be more on an index that has become fragmented over a period of time with many updates and no optimizations. Optimizations require a much longer time than does the distribution of an optimized collection to all slaves.
Segments	The number of files in a collection.
mergeFactor	A parameter that controls the number of files (segments) in a collection. For example, when mergeFactor is set to 3, Solr will fill one segment with documents until the limit maxBufferedDocs is met, then it will start a new segment. When the number of segments specified by mergeFactor is reached—in this example, 3—then Solr will merge all the segments into a single index file, then begin writing new documents to a new segment.
Snapshot	A directory containing hard links to the data files. Snapshots are distributed from the master server when the slaves pull them, "smartcopying" the snapshot directory that contains the hard links to the most recent collection data files.

Configuring the Replication RequestHandler on a Master Server

The example below shows how to configure the Replication RequestHandler on a master server.

```

<requestHandler name="/replication" class="solr.ReplicationHandler" >
  <lst name="master">

    <!--Replicate on 'optimize'. Other values can be 'commit', 'startup'.
      It is possible to have multiple entries of this config string-->

    <str name="replicateAfter">optimize</str>

    <!--Create a backup after 'optimize'. Other values can be 'commit', 'startup'.
      It is possible to have multiple entries of this config string.
      Note that this is just for backup, replication does not require this. -->

    <!-- <str name="backupAfter">optimize</str> -->

    <!--If configuration files need to be replicated give the names here, separated
  by comma -->

    <str name="confFiles">schema.xml,stopwords.txt,elevate.xml</str>

    <!--The default value of reservation is 10 secs. Normally , you should not need
  to specify this -->

    <str name="commitReserveDuration">00:00:10</str>
  </lst>
</requestHandler>

```

- If your commits are very frequent and network is particularly slow, you can tweak an extra attribute `<str name="commitReserveDuration">00:00:10</str>`. This is roughly the time taken to download 5MB from master to slave. Default is 10 seconds.
- If you are using **startup** option for `replicateAfter`, it is necessary to have a **commit/optimize** entry also, if you want to trigger replication on future commits/optimizes. If only the **startup** option is given, replication will not be triggered on subsequent commits/optimizes after it is done for the first time at the start.

Replicating solrconfig.xml

In the configuration file on the master server, include a line like the following:

```
<str name="confFiles">solrconfig_slave.xml:solrconfig.xml,x.xml,y.xml</str>
```

This ensures that the local configuration `solrconfig_slave.xml` will be saved as `solrconfig.xml` on the slave. All other files will be saved with their original names.

On the master server, the file name of the slave configuration file can be anything, as long as the name is correctly identified in the `confFiles` string; then it will be saved as whatever file name appears after the colon ':':

Configuring the Replication RequestHandler on a Slave Server

The code below shows how to configure a `ReplicationHandler` on a slave.

```
<requestHandler name="/replication" class="solr.ReplicationHandler" >
  <lst name="slave">

    <!--fully qualified url for the replication handler of master. It is possible
to pass on this as
      a request param for the fetchindex command-->

    <str name="masterUrl">http://remote_host:port/solr/corename/replication</str>

    <!--Interval in which the slave should poll master .Format is HH:mm:ss . If
this is absent slave does not
      poll automatically.

    But a fetchindex can be triggered from the admin or the http API -->

    <str name="pollInterval">00:00:20</str>

    <!-- THE FOLLOWING PARAMETERS ARE USUALLY NOT REQUIRED-->

    <!--to use compression while transferring the index files. The possible values
are internal|external
      if the value is 'external' make sure that your master Solr has the settings to
honor the
      accept-encoding header.
      See here for details: http://wiki.apache.org/solr/SolrHttpCompression
      If it is 'internal' everything will be taken care of automatically.
      USE THIS ONLY IF YOUR BANDWIDTH IS LOW . THIS CAN ACTUALLY SLOWDOWN
      REPLICATION IN A LAN-->

    <str name="compression">internal</str>

    <!--The following values are used when the slave connects to the master to
```

```

download the index files.
    Default values implicitly set as 5000ms and 10000ms respectively. The user
DOES NOT need to specify
    these unless the bandwidth is extremely low or if there is an extremely high
latency-->

    <str name="httpConnTimeout">5000</str>
    <str name="httpReadTimeout">10000</str>

    <!-- If HTTP Basic authentication is enabled on the master, then the slave can
be
        configured with the following -->

    <str name="httpBasicAuthUser">username</str>
    <str name="httpBasicAuthPassword">password</str>
</lst>
</requestHandler>

```

 If you are not using cores, then you simply omit the `corename` parameter above in the `masterUrl`. To ensure that the URL is correct, just hit the URL with a browser. You must get a status OK response.

Setting Up a Repeater with the ReplicationHandler

A master may be able to serve only so many slaves without affecting performance. Some organizations have deployed slave servers across multiple data centers. If each slave downloads the index from a remote data center, the resulting download may consume too much network bandwidth. To avoid performance degradation in cases like this, you can configure one or more slaves as repeaters. A repeater is simply a node that acts as both a master and a slave.

- To configure a server as a repeater, the definition of the Replication `requestHandler` in the `solrconfig.xml` file must include file lists of use for both masters and slaves.
- Be sure to set the `replicateAfter` parameter to `commit`, even if `replicateAfter` is set to `optimize` on the main master. This is because on a repeater (or any slave), a `commit` is called only after the index is downloaded. The `optimize` command is never called on slaves.
- Optionally, one can configure the repeater to fetch compressed files from the master through the `compression` parameter to reduce the index download time.

Here's an example of a `ReplicationHandler` configuration for a repeater:

```

<requestHandler name="/replication" class="solr.ReplicationHandler">
  <lst name="master">
    <str name="replicateAfter">commit</str>
    <str name="confFiles">schema.xml,stopwords.txt,synonyms.txt</str>
  </lst>
  <lst name="slave">
    <str name="masterUrl">http://master.solr.company.com:8983/solr/replication</str>
    <str name="pollInterval">00:00:60</str>
  </lst>
</requestHandler>

```

Commit and Optimize Operations

When a commit or optimize operation is performed on the master, the RequestHandler reads the list of file names which are associated with each commit point. This relies on the `replicateAfter` parameter in the configuration to decide which types of events should trigger replication.

replicateAfter Setting on the Master	Description
commit	Triggers replication whenever a commit is performed on the master index.
optimize	Triggers replication whenever the master index is optimized.
startup	Triggers replication whenever the master index starts up.

The `replicateAfter` parameter can accept multiple arguments. For example:

```

<str name="replicateAfter">startup</str>
<str name="replicateAfter">commit</str>
<str name="replicateAfter">optimize</str>

```

Slave Replication

The master is totally unaware of the slaves. The slave continuously keeps polling the master (depending on the `pollInterval` parameter) to check the current index version the master. If the slave finds out that the master has a newer version of the index it initiates a replication process.

The steps are as follows:

- The slave issues a `filelist` command to get the list of the files. This command returns the names of the files as well as some metadata (for example, size, a lastmodified timestamp, an alias if any).

- The slave checks with its own index if it has any of those files in the local index. It then runs the `filecontent` command to download the missing files. This uses a custom format (akin to the HTTP chunked encoding) to download the full content or a part of each file. If the connection breaks in between, the download resumes from the point it failed. At any point, the slave tries 5 times before giving up a replication altogether.
- The files are downloaded into a temp directory, so that if either the slave or the master crashes during the download process, no files will be corrupted. Instead, the current replication will simply abort.
- After the download completes, all the new files are 'mov'ed to the live index directory and the file's timestamp is same as its counterpart in on the master master.
- A commit command is issued on the slave by the Slave's ReplicationHandler and the new index is loaded.

Replicating Configuration Files

To replication configuration files, list them using using the `confFiles` parameter. Only files found in the `conf` directory of the master's Solr instance will be replicated

Solr replicates configuration files only when the index itself is replicated. That means even if a configuration file is changed on the master, that file will be replicated only after there is a new commit/optimize on master's index.

Unlike the index files, where the timestamp is good enough to figure out if they are identical, configuration files are compared against their checksum. The `schema.xml` files (on master and slave) are judged to be identical if their checksums are identical.

As a precaution when replicating configuration files, Solr copies configuration files to a temporary directory before moving them into their ultimate location in the `conf` directory. The old configuration files are then renamed and kept in the same `conf/` directory. The ReplicationHandler does not automatically clean up these old files.

If a replication involved downloading of at least one configuration file, the ReplicationHandler issues a `core-reload` command instead of a `commit` command.

Resolving Corruption Issues on Slave Servers

If documents are added to the slave, then the slave is no longer in sync with its master. However, the slave will not undertake any action to put itself in sync, until the master has new index data. When a commit operation takes place on the master, the index version of the master becomes different from that of the slave. The slave then fetches the list of files and finds that some of the files present on the master are also present in the local index but with different sizes and timestamps. This means that the master and slave have incompatible indexes. To correct this problem, the slave then copies all the index files from master to a new index directory and asks the core to load the fresh index from the new directory.

HTTP API Commands for the ReplicationHandler

You can use the HTTP commands below to control the ReplicationHandler's operations.

Command	Description
<code>http://master_host:port/solr/replication?command=enablereplication</code>	Enables replication on the master for all its slaves.
<code>http://master_host:port/solr/replication?command=disablereplication</code>	Disables replication on the master for all its slaves.
<code>http://host:port/solr/replication?command=indexversion</code>	Returns the version of the latest replicatable index on the specified master or slave
<code>http://slave_host:port/solr/replication?command=fetchindex</code>	<p>Forces the specified slave to fetch a copy of the index from its master.</p> <p>If you like, you can pass an extra attribute such as <code>masterUrl</code> or <code>compression</code> (or any other parameter which is specified in the <code><lst name="slave"></code> tag) to do a one time replication from a master. This obviates the need for hard-coding the master in the slave.</p>
<code>http://slave_host:port/solr/replication?command=abortfetch</code>	Aborts copying an index from a master to the specified slave.
<code>http://slave_host:port/solr/replication?command=enablepoll</code>	Enables the specified slave to poll for changes on the master.
<code>http://slave_host:port/solr/replication?command=disablepoll</code>	Disables the specified slave from polling for changes on the master.
<code>http://slave_host:port/solr/replication?command=details</code>	Retrieves configuration details and current status.

<code>http://host:port/solr/replication?command=filelist&indexversion=<index-version-number></code>	Retrieves a list of Lucene files present in the specified host's index. You can discover the version number of the index by running the <code>indexversion</code> command.
<code>http://master_host:port/solr/replication?command=backup</code>	Creates a backup on master if there are committed index data in the server; otherwise, does nothing. This command is useful for making periodic backups.

Using the Replication Dashboard

The Solr Replication Dashboard, which is accessible through the Distribution link on the Admin Web interfaces, shows the following information related to replication managed through the Replication Handler:

- status of current replication
- percentage/size downloaded/to be downloaded
- the name of the current file being downloaded
- the time taken compared to the time remaining

The figure below shows the Replication Dashboard for a slave server.

Solr replication (example) Slave

drews-macbook:8984
 cwd=/Users/drewwheeler/apache-solr-3.4.0/example8984 SolrHome=solr/./

(WHAT IS THIS PAGE?)

Master	http://localhost:8983/solr/replication
	Latest Index Version:null, Generation: null
	Replicable Index Version:1317325247607, Generation: 3
Poll Interval	00:00:60
Local Index	Index Version: 1317325247607, Generation: 3
	Location: /Users/drewwheeler/apache-solr-3.4.0/example8984/solr/data/index
	Size: 19.29 KB
	Times Replicated Since Startup: 33
	Previous Replication Done At: Wed Oct 19 22:13:00 PDT 2011
	Config Files Replicated At: null
	Config Files Replicated: null
	Times Config Files Replicated Since Startup: null
	Next Replication Cycle At: Wed Oct 19 22:14:00 PDT 2011
Controls	<input type="button" value="Disable Poll"/>
	<input type="button" value="Replicate Now"/>

Current Time: Wed Oct 19 22:13:33 PDT 2011
 Server Start At: Wed Oct 19 22:12:43 PDT 2011

[RETURN TO ADMIN PAGE](#)

The Replication Dashboard reports details of the master-slave configuration and offers controls for managing the replication.

You can perform the following actions from the Replication Dashboard:

- Enable/Disable polling
- Force-start replication (sometimes useful for making a backup copy of an index)
- Abort an ongoing replication process

Index Replication using ssh and rsync

Solr supports `ssh/rsync`-based replication. *This mechanism only works on systems that support removing open hard links.*

Solr distribution is similar in concept to database replication. All collection changes come to one master Solr server. All production queries are done against query slaves. Query slaves receive all their collection changes indirectly — as new versions of a collection which they pull from the master. These collection downloads are polled for on a cron'd basis.

A collection is a directory of many files. Collections are distributed to the slaves as snapshots of these files. Each snapshot is made up of hard links to the files so copying of the actual files is not necessary when snapshots are created. Lucene only *significantly* rewrites files following an optimization command. Generally, once a file is written, it will change very little, if at all. This makes the underlying transport of rsync very useful. Files that have already been transferred and have not changed do not need to be re-transferred with the new edition of a collection.

The Snapshot and Distribution Process

Here are the steps that Solr follows when replicating an index:

1. The **snapshotter** command takes snapshots of the collection on the master. It runs when invoked by Solr after it has done a commit or an optimize.
2. The **snappuller** command runs on the query slaves to pull the newest snapshot from the master. This is done via rsync in daemon mode running on the master for better performance and lower CPU utilization over rsync using a remote shell program as the transport.
3. The **snapinstaller** runs on the slave after a snapshot has been pulled from the master. This signals the local Solr server to open a new index reader, then auto-warming of the cache(s) begins (in the new reader), while other requests continue to be served by the original index reader. Once auto-warming is complete, Solr retires the old reader and directs all new queries to the newly cache-warmed reader.
4. All distribution activity is logged and written back to the master to be viewable on the distribution page of its GUI.
5. Old versions of the index are removed from the master and slave servers by a cron'd **snapcleaner**.

If you are building an index from scratch, distribution is the final step of the process.

Manual copying of index files is not recommended; however, running distribution commands manually (that is, not relying on `crond` to run them) is perfectly fine.

Snapshot Directories

Snapshots are stored in directories whose names follow this format: `snapshot_YYYYmmddHHMMSS`

All the files in the index directory are hard links to the latest snapshot. This design offers these advantages:

- The Solr implementation can keep multiple snapshots on each host without needing to keep multiple copies of index files that have not changed.
- File copying from master to slave is very fast.
- Taking a snapshot is very fast as well.

Solr Distribution Scripts

For the Solr distribution scripts, the name of the index directory is defined either by the environment variable `data_dir` in the configuration file `solr/conf/scripts.conf` or the command line argument `-d`. It should match the value used by the Solr server which is defined in `solr/conf/solrconfig.xml`.

All Solr collection distribution scripts are bundled in a Solr release and reside in the directory `solr/src/scripts`. Lucid Imagination recommends that you install the scripts in a `solr/bin/` directory.

Collection distribution scripts create and prepare for distribution a snapshot of a search collection after each commit and optimize request if the `postCommit` and `postOptimize` event listener is configured in `solrconfig.xml` to execute **snapshotter**.

The **snapshotter** script creates a directory `snapshot.<ts>`, where `<ts>` is a timestamp in the format, `yyyymmddHHMMSS`. It contains hard links to the data files.

Snapshots are distributed from the master server when the slaves pull them, "smartcopying" the snapshot directory that contains the hard links to the most recent collection data files.

Name	Description
snapshotter	Creates a snapshot of a collection. Snapshotter is normally configured to run on the master Solr server when a commit or optimize happens. Snapshotter can also be run manually, but one must make sure that the index is in a consistent state, which can only be done by pausing indexing and issuing a commit.
snappuller	A shell script that runs as a <code>cron</code> job on a slave Solr server. The script looks for new snapshots on the master Solr server and pulls them.
snappuller-enable	Creates the file <code>solr/logs/snappuller-enabled</code> , whose presence enables snappuller.
snapinstaller	Installs the latest snapshot (determined by the timestamp) into the place, using hard links (similar to the process of taking a snapshot). Then <code>solr/logs/snapshot.current</code> is written and scp'd (secure copied) back to the master Solr server. snapinstaller then triggers the Solr server to open a new Searcher.
snapcleaner	Runs as a <code>cron</code> job to remove snapshots more than a configurable number of days old or all snapshots except for the most recent <code>n</code> number of snapshots. Also can be run manually.
rsyncd-start	Starts the rsyncd daemon on the master Solr server which handles collection distribution requests from the slaves.
rsyncd daemon	Efficiently synchronizes a collection—between master and slaves—by copying only the files that actually changed. In addition, rsync can optionally compress data before transmitting it.

rsyncd-stop	Stops the rsyncd daemon on the master Solr server. The stop script then makes sure that the daemon has in fact exited by trying to connect to it for up to 300 seconds. The stop script exits with error code 2 if it fails to stop the rsyncd daemon.
rsyncd-enable	Creates the file <code>solr/logs/rsyncd-enabled</code> , whose presence allows the rsyncd daemon to run, allowing replication to occur.
rsyncd-disable	Removes the file <code>solr/logs/rsyncd-enabled</code> , whose absence prevents the rsyncd daemon from running, preventing replication.

For more information about usage arguments and syntax see the [SolrCollectionDistributionScripts](#) page on the Solr Wiki.

Solr Distribution-related Cron Jobs

The distribution process is automated through the use of cron jobs. The cron jobs should run under the user ID that the Solr server is running under.

Cron Job	Description
snapcleaner	<p>The snapcleaner job should be run out of <code>cron</code> at the regular basis to clean up old snapshots. This should be done on both the master and slave Solr servers. For example, the following <code>cron</code> job runs everyday at midnight and cleans up snapshots 8 days and older:</p> <pre>0 0 * * * <solr.solr.home>/solr/bin/snapcleaner -D 7</pre> <p>Additional cleanup can always be performed on-demand by running <code>snapcleaner</code> manually.</p>
snappuller snapinstaller	<p>On the slave Solr servers, <code>snappuller</code> should be run out of <code>cron</code> regularly to get the latest index from the master Solr server. It is a good idea to also run <code>snapinstaller</code> with <code>snappuller</code> back-to-back in the same <code>crontab</code> entry to install the latest index once it has been copied over to the slave Solr server.</p>

For example, the following cron job runs every 5 minutes to keep the slave Solr server in sync with the master Solr server:

```
0,5,10,15,20,25,30,35,40,45,50,55 * * * * *
<solr.solr.home>/solr/bin/snappuller;<solr.solr.home>/solr/bin/snapinstaller
```

Modern cron allows this to be shortened to `*/5 * * * * . . .`

Commit and Optimization

On a very large index, adding even a few documents then running an optimize operation causes the complete index to be rewritten. This consumes a lot of disk I/O and impacts query performance. Optimizing a very large index may even involve copying the index twice and calling optimize at the beginning *and* at the end. If some documents have been deleted, the first optimize call will rewrite the index even before the second index is merged.

Optimization is an I/O intensive process, as the entire index is read and re-written in optimized form. Anecdotal data shows that optimizations on modest server hardware can take around 5 minutes per GB, although this obviously varies considerably with index fragmentation and hardware bottlenecks. We do not know what happens to query performance on a collection that has not been optimized for a long time. We *do* know that it will get worse as the collection becomes more fragmented, but how much worse is very dependent on the manner of updates and commits to the collection. The setting of the `mergeFactor` attribute affects performance as well. Dividing a large index with millions of documents into even as few as five segments may degrade search performance by as much as 15-20%.

We are presuming optimizations should be run once following large *batch-like* updates to the collection and/or once a day.

Distribution and Optimization

The time required to optimize a master index can vary dramatically. A small index may be optimized in minutes. A very large index may take hours. The variables include the size of the index and the speed of the hardware.

Distributing a newly optimized collection may take only a few minutes or up to an hour or more, again depending on the size of the index and the performance capabilities of network connections and disks. During optimization the machine is under load and does not process queries very well. Given a schedule of updates being driven a few times an hour to the slaves, we cannot run an optimize with every committed snapshot. We do recommend that an optimize be run on the master at least once a day.

Copying an optimized collection means that the **entire** collection will need to be transferred during the next snappull. This is a large expense, but not nearly as huge as running the optimize everywhere. Consider this example: on a three-slave one-master configuration, distributing a newly-optimized collection takes approximately 80 seconds *total*. Rolling the change across a tier would require approximately ten minutes per machine (or machine group). If this optimize were rolled across the query tier, and if each collection being optimized were disabled and not receiving queries, a rollout would take at least twenty minutes and potentially as long as an hour and a half. Additionally, the files would need to be synchronized so that the *following* rsync, snappull would not think that the independently optimized files were different in any way. This would also leave the door open to independent corruption of collections instead of each being a perfect copy of the master.

Optimizing on the master allows for a straight-forward optimization operation. No query slaves need to be taken out of service. The optimized collection can be distributed in the background as queries are being normally serviced. The optimization can occur at any time convenient to the application providing collection updates.

Performance Tuning for Script-based Replication

Because fetching a master index uses the rsync utility, which transfers only the segments that have changed, replication is normally very fast. However, if the master server has been optimized, then rsync may take a long time, because many segments will have been changed in the process of optimization.

- If replicating to multiple slaves consumes too much network bandwidth, consider the use of a repeater.
- Make sure that slaves do not pull from the master so frequently that a previous replication is still running when a new one is started. In general, it's best to allow at least a minute for the replication process to complete. But in configurations with low network bandwidth or a very large index, even more time may be required.

Combining Distribution and Replication

When your index is too large for a single machine and you have a query volume that single shards cannot keep up with, it's time to replicate each shard in your distributed search setup.

The idea is to combine distributed search with replication. As shown in the figure below, a combined distributed-replication configuration features a master server for each shard and then 1- n slaves that are replicated from the master. As in a standard replicated configuration, the master server handles updates and optimizations without adversely affecting query handling performance.

Query requests should be load balanced across each of the shard slaves. This gives you both increased query handling capacity and fail-over backup if a server goes down.

Distributed + Replication

A Solr configuration combining both replication and master-slave distribution.

None of the master shards in this configuration know about each other. You index to each master, the index is replicated to each slave, and then searches are distributed across the slaves, using one slave from each master/slave shard.

For high availability you can use a load balancer to set up a virtual IP for each shard's set of slaves. If you are new to load balancing, HAProxy (<http://haproxy.1wt.eu/>) is a good open source software load-balancer. If a slave server goes down, a good load-balancer will detect the failure using some technique (generally a heartbeat system), and forward all requests to the remaining live slaves that served with the failed slave. A single virtual IP should then be set up so that requests can hit a single IP, and get load balanced to each of the virtual IPs for the search slaves.

With this configuration you will have a fully load balanced, search-side fault-tolerant system (Solr does not yet support fault-tolerant indexing). Incoming searches will be handed off to one of the functioning slaves, then the slave will distribute the search request across a slave for each of the shards in your configuration. The slave will issue a request to each of the virtual IPs for each shard, and the load balancer will choose one of the available slaves. Finally, the results will be combined into a single results set and returned. If any of the slaves go down, they will be taken out of rotation and the remaining slaves will be used. If a shard master goes down, searches can still be served from the slaves until you have corrected the problem and put the master back into production.

Merging Indexes

If you need to combine indexes from two different projects or from multiple servers previously used in a distributed configuration, you can use either the `IndexMergeTool` included in `lucene-misc` or the `CoreAdminHandler`.

To merge indexes, they must meet these requirements:

- The two indexes must be compatible: their schemas should include the same fields and they should analyze fields the same way.
- The indexes must not include duplicate data.

Optimally, the two indexes should be built using the same schema.

Using IndexMergeTool

To merge the indexes, do the following:

1. Find the lucene JAR file that your version of Solr is using. You can do this by copying your `solr.war` file somewhere and unpacking it (`jar xvf solr.war`). Your lucene JAR file should be in `WEB-INF/lib`. It is probably called something like `lucene-core-2007-05-20_00-04-53.jar`.
2. Copy it somewhere easy to find.
3. Download a copy of Lucene from <http://www.lucidimagination.com/downloads> and unpack it. The file you're interested in is `contrib/misc/lucene-misc-VERSION.jar`.
4. Make sure that both indexes you want to merge are closed.
5. Issue this command:

```
java -cp /path/to/lucene-core-VERSION.jar:/path/to/lucene-misc-VERSION.jar
org/apache/lucene/misc/IndexMergeTool
/path/to/newindex
/path/to/index1
/path/to/index2
```

This will create a new index at `/path/to/newindex` that contains both `index1` and `index2`.

6. Copy this new directory to the location of your application's solr index (move the old one aside first, of course) and start Solr.

For example:

```
java -cp /tmp/lucene-core-2007-05-20_00-04-53.jar:  
./lucene-2.2.0/contrib/misc/lucene-misc-2.2.0.jarorg/apache/lucene/misc/IndexMergeTool  
  
./newindex  
./app1/solr/data/index  
./app2/solr/data/index
```

Using CoreAdmin

This method uses the [CoreAdminHandler](#) with either the `indexDir` or `srcCore` parameters.

The `indexDir` parameter is used to define the path to the indexes for the cores that should be merged, and merge them into a 3rd core that must already exist prior to initiation of the merge process. The indexes must exist on the disk of the Solr host, which may make using this in a distributed environment cumbersome. With the `indexDir` parameter, a commit should be called on the cores to be merged (so the `IndexWriter` will close), and no writes should be allowed on either core until the merge is complete. If writes are allowed, corruption may occur on the merged index. Once complete, a commit should be called on the merged core to make sure the changes are visible to searchers.

The following example shows how to construct the merge command with `indexDir`:

```
http://localhost:8983/solr/admin/cores?action=mergeindexes&core=core0&indexDir=/home
```

In this example, `core` is the new core that is created prior to calling the merge process.

The `srcCore` parameter is used to call the cores to be merged by name instead of defining the path. The cores do not need to exist on the same disk as the Solr host, and the merged core does not need to exist prior to issuing the command. `srcCore` also protects against corruption during creation of the merged core index, so writes are still possible while the merge occurs. However, `srcCore` can only merge Solr Cores - indexes built directly with Lucene should be merged with either the `IndexMergeTool` or the `indexDir` parameter.

The following example shows how to construct the merge command with `srcCore`:

```
http://localhost:8983/solr/admin/cores?action=mergeindexes&core=core0&srcCore=core1&
```

Client APIs

This section discusses the available client APIs for Solr. It covers the following topics:

[Introduction to Client APIs](#): A conceptual overview of Solr client APIs.

[Choosing an Output Format](#): Information about choosing a response format in Solr.

[Using JavaScript](#): Explains why you a client API is not needed for JavaScript responses.

[Using Python](#): Information about Python and JSON reponses.

[Client API Lineup](#): A list of all Solr Client APIs, with links.

[Using SolrJ](#): Detailed information about SolrJ, an API for working with Java applications.

[Using Solr From Ruby](#): Detailed information about using Solr with Ruby applications.

[MBean Request Handler](#): Describes the MBean request handler for programmatic access to Solr server statistics and information.

Introduction to Client APIs

At its heart, Solr is a Web application, but because it is built on open protocols, any type of client application can use Solr.

HTTP is the fundamental protocol used between client applications and Solr. The client makes a request and Solr does some work and provides a response. Clients use requests to ask Solr to do things like perform queries or index documents.

Client applications can reach Solr by creating HTTP requests and parsing the HTTP responses. Client APIs encapsulate much of the work of sending requests and parsing responses, which makes it much easier to write client applications.

Clients use Solr's five fundamental operations to work with Solr. The operations are query, index, delete, commit, and optimize.

Queries are executed by creating a URL that contains all the query parameters. Solr examines the request URL, performs the query, and returns the results. The other operations are similar, although in certain cases the HTTP request is a POST operation and contains information beyond whatever is included in the request URL. An index operation, for example, may contain a document in the body of the request.

Solr also features an `EmbeddedSolrServer` that offers a Java API without requiring an HTTP connection. For details, see [Using SolrJ](#).

Choosing an Output Format

Many programming environments are able to send HTTP requests and retrieve responses. Parsing the responses is a slightly more thorny problem. Fortunately, Solr makes it easy to choose an output format that will be easy to handle on the client side.

Specify a response format using the `wf` parameter in a query. The available response formats are documented in [Response Writers](#).

Most client APIs hide this detail for you, so for many types of client applications, you won't ever have to specify a `wf` parameter. In JavaScript, however, the interface to Solr is a little closer to the metal, so you will need to add this parameter yourself.

Using JavaScript

Using Solr from JavaScript clients is so straightforward that it deserves a special mention. In fact, it is so straightforward that there is no client API. You don't need to install any packages or configure anything.

HTTP requests can be sent to Solr using the standard `XMLHttpRequest` mechanism.

Out of the box, Solr can send [JavaScript Object Notation \(JSON\) responses](#), which are easily interpreted in JavaScript. Just add `wt=json` to the request URL to have responses sent as JSON.

For more information and an excellent example, read the SolJSON page on the Solr Wiki:

<http://wiki.apache.org/solr/SolJSON>

Using Python

Solr includes an output format specifically for [Python](#), but [JSON output](#) is a little more robust.

Simple Python

Making a query is a simple matter. First, tell Python you will need to make HTTP connections.

```
from urllib2 import *
```

Now open a connection to the server and get a response. The `wt` query parameter tells Solr to return results in a format that Python can understand.

```
connection = urlopen(
    'http://localhost:8983/solr/select?q=cheese&wt=python')
response = eval(connection.read())
```

Now interpreting the response is just a matter of pulling out the information that you need.

```
print response\['response'\]\['numFound'\], "documents found."

# Print the name of each document.

for document in response\['response'\]\['docs'\]:
    print "  Name =", document\['name'\]
```

Python with JSON

JSON is a more robust response format, but you will need to add a Python package in order to use it. At a command line, install the `simplejson` package like this:

```
$ sudo easy_install simplejson
```

Once that is done, making a query is nearly the same as before. However, notice that the `wt` query parameter is now `json`, and the response is now digested by `simplejson.load()`.

```
from urllib2 import *
import simplejson
connection = urlopen('http://localhost:8983/solr/select?q=cheese&wt=json')
response = simplejson.load(connection)
print response['response']['numFound'], "documents found."

# Print the name of each document.

for document in response['response']['docs']:
    print " Name =", document['name']
```

Client API Lineup

The Solr Wiki contains a list of client APIs at <http://wiki.apache.org/solr/IntegratingSolr>.

Here is the list of client APIs, current at this writing (November 2011):

Name	Environment	URL
SolRuby	Ruby	http://wiki.apache.org/solr/SolRuby
DelSolr	Ruby	http://delsolr.rubyforge.org/
acts_as_solr	Rails	http://acts-as-solr.rubyforge.org/ , http://rubyforge.org/projects/background-solr/
Flare	Rails	http://wiki.apache.org/solr/Flare
SolPHP	PHP	http://wiki.apache.org/solr/SolPHP
SolrJ	Java	http://wiki.apache.org/solr/SolJava
Python API	Python	http://wiki.apache.org/solr/SolPython
PySolr	Python	http://code.google.com/p/pysolr/
SolPerl	Perl	http://wiki.apache.org/solr/SolPerl
Solr.pm	Perl	http://search.cpan.org/~garafola/Solr-0.03/lib/Solr.pm
SolrForrest	Forrest/Cocoon	http://wiki.apache.org/solr/SolrForrest
SolrSharp	C#	http://www.codeplex.com/solrsharp
SolColdfusion	ColdFusion	http://solcoldfusion.riaforge.org/
SolrNet	.NET	http://code.google.com/p/solrnet/
AJAX Solr	AJAX	http://github.com/evolvingweb/ajax-solr/wiki

Using SolrJ

SolrJ (also sometimes known as SolJava) is an API that makes it easy for Java applications to talk to Solr. SolrJ hides a lot of the details of connecting to Solr and allows your application to interact with Solr with simple high-level methods.

The center of SolrJ is the `org.apache.solr.client.solrj` package, which contains just five main classes. Begin by creating a `SolrServer`, which represents the Solr instance you want to use. Send `SolrRequests` or `SolrQueries` and get back `SolrResponses`.

`SolrServer` is abstract, so to connect to a remote Solr instance, you'll actually create an instance of `org.apache.solr.client.solrj.impl.CommonsHttpSolrServer`, which knows how to use HTTP to talk to Solr.

```
String urlString = "http://localhost:8983/solr";
SolrServer solr = new CommonsHttpSolrServer(urlString);
```

Creating a `SolrServer` does not make a network connection - that happens later when you perform a query or some other operation — but it will throw `MalformedURLException` if you give it a bad URL string.

Once you have a `SolrServer`, you can use it by calling methods like `query()`, `add()`, and `commit()`.

For more information on SolrJ, see <https://wiki.apache.org/solr/Solrj>.

Building and Running SolrJ Applications

The SolrJ API is included with Solr, so you do not have to download or install anything else. However, in order to build and run applications that use SolrJ, you have to add some libraries to the classpath.

At build time, the examples presented with this section require the following libraries in the classpath (all paths are relative to the root of the Solr installation).

```
apache-solr-common-3.4.0.jar
apache-solr-solrj-3.4.0.jar
```

At run time, the examples in this section require the following libraries:

- `apache-solr-common-3.4.0.jar`
- `apache-solr-solrj-3.4.0.jar`
- `solrj-lib/commons-httpclient-3.4.jar`
- `solrj-lib/commons-logging-1.0.4.jar`
- `solrj-lib/commons-codec-3.4.jar`

The Ant script bundled with this sections' examples includes the libraries as appropriate when building and running.

You can sidestep a lot of the messing around with the JAR files by using Maven instead of Ant. All you will need to do to include SolrJ in your application is to put the following dependency in the project's `pom.xml`:

```
<dependency>
  <groupId>org.apache.solr</groupId>
  <artifactId>solr-solrj</artifactId>
  <version>3.4.0</version>
</dependency>
```

If you are worried about the SolrJ libraries expanding the size of your client application, you can use a code obfuscator like ProGuard to remove APIs that you are not using. ProGuard is available [here](http://proguard.sourceforge.net/):

<http://proguard.sourceforge.net/>

Setting XMLResponseParser

SolrJ uses a binary format, rather than XML, as its default format. Users of earlier Solr releases who wish to continue working with XML must explicitly set the parser to the `XMLResponseParser`, like so:

```
server.setParser(new XMLResponseParser());
```

Performing Queries

Use `query()` to have Solr search for results. You have to pass a `SolrQuery` object that describes the query, and you will get back a `QueryResponse` (from the `org.apache.solr.client.solrj.response` package).

`SolrQuery` has methods that make it easy to add parameters to choose a request handler and send parameters to it. Here is a very simple example that uses the default request handler and sets the `q` parameter:

```
SolrQuery parameters = new SolrQuery();
parameters.set("q", mQueryString);
```

To choose a different request handler, for example, just set the `qt` parameter like this:

```
parameters.set("qt", "/spellCheckCompRH");
```

Once you have your SolrQuery set up, submit it with `query()`:

```
QueryResponse response = solr.query(parameters);
```

The client make a network connection, the query is sent, Solr processes the query, and the response is sent and parsed into a QueryResponse.

The QueryResponse is a collection of documents that satisfy the query parameters. You can retrieve the documents directly with `getResults()` and you can call other methods to find out information about highlighting or facets.

```
SolrDocumentList list = response.getResults();
```

Indexing Documents

Other operations are just as simple. To index (add) a document, all you need to do is create a SolrInputDocument and pass it along to the SolrServer's `add()` method.

```
String urlString = "http://localhost:8983/solr";
SolrServer solr = new CommonsHttpSolrServer(urlString);
SolrInputDocument document = new SolrInputDocument();
document.addField("id", "552199");
document.addField("name", "Gouda cheese wheel");
document.addField("price", "49.99");
UpdateResponse response = solr.add(document);
```

Remember to commit your changes!

```
solr.commit();
```

Uploading Content in XML or Binary Formats

SolrJ lets you upload content in XML and binary formats instead of the default XML format. Use the following to upload using Binary format. this is the same format which SolrJ uses to fetch results.

```
server.setRequestWriter(new BinaryRequestWriter());
```

EmbeddedSolrServer

The [EmbeddedSolrServer](#) provides the Java interface described above without requiring an HTTP connection. This is the recommended approach if you need to use Solr in an embedded application. This approach enables you to work with the same Java interface whether or not you have access to HTTP.

 **EmbeddedSolrServer** works only with handlers registered in `solrconfig.xml`. RequestHandler must be mapped to `/update` for a request to function. For information about configuring handlers in `solrconfig.xml`, see [Configuring solrconfig.xml](#).

Note that the following property could be set through JVM level arguments:

```
System.setProperty("solr.solr.home",
"/home/shalinsmangar/work/oss/branch-1.3/example/solr");
CoreContainer.Initializer initializer = new CoreContainer.Initializer();
CoreContainer coreContainer = initializer.initialize();
EmbeddedSolrServer server = new EmbeddedSolrServer(coreContainer, "");
```

If you want to use [MultiCore](#) features (which are described in [Configuring solr.xml](#)), then you should use this:

```
File home = new File( "/path/to/solr/home" );
File f = new File( home, "solr.xml" );
CoreContainer container = new CoreContainer();
container.load( "/path/to/solr/home", f );
EmbeddedSolrServer server = new EmbeddedSolrServer( container, "core name as defined in
solr.xml" );
...
```

Using the StreamingUpdateSolrServer

If you are working with Java, you can take advantage of the `StreamingUpdateSolrServer` to perform bulk updates at high speed. `StreamingHttpSolrServer` buffers all added documents and writes them into open HTTP connections. This class is thread safe. Although any `SolrServer` request can be made with this implementation, it is only recommended to use the `StreamingUpdateSolrServer` for `/update` requests.

You can learn more about the `StreamingUpdateSolrServer` here:

<http://lucene.apache.org/solr/api/org/apache/solr/client/solrj/impl/StreamingUpdateSolrServer.htm>

More Information

As you begin developing with SolrJ, you will find the API documentation indispensable. It is available online at the Apache Lucene site:

<http://lucene.apache.org/solr/api/solrj/index.html>

For more information about using SolrJ, read the page at the Solr Wiki:

<http://wiki.apache.org/solr/Solrj>

The Solr Wiki also contains another example which demonstrates setting `qt`:

<http://wiki.apache.org/solr/SolJava>

Using Solr From Ruby

For Ruby applications, the `solr-ruby` gem encapsulates the fundamental Solr operations.

At a command line, install `solr-ruby` as follows:

```
$ gem install solr-ruby
Bulk updating Gem source index for: http://gems.rubyforge.org
Successfully installed solr-ruby-0.0.8
1 gem installed
Installing ri documentation for solr-ruby-0.0.8...
Installing RDoc documentation for solr-ruby-0.0.8...
```

This gives you a `Solr::Connection` class that makes it easy to add documents, perform queries, and do other Solr stuff.

`Solr-ruby` takes advantage of Solr's Ruby response writer, which is a subclass of the JSON response writer. This response writer sends information from Solr to Ruby in a form that Ruby can understand and use directly.

Performing Queries

To perform queries, you just need to get a `Solr::Connection` and call its `query` method. Here is a script that looks for cheese. The return value from `query()` is an array of documents, which are dictionaries, so the script iterates through each document and prints out a few fields.

```
require 'rubygems'
require 'solr'
solr = Solr::Connection.new('http://localhost:8983/solr')
response = solr.query('cheese')
response.each do |hit|
  puts hit\['id'\] + ' ' + hit\['name'\] + ' ' + hit\['price'\].to_s
end
```

An example run looks like this:

```
$ ruby query.rb
551299 Gouda cheese wheel 49.99
123 Fresh mozzarella cheese
```

Indexing Documents

Indexing is just as simple. You have to get the `Solr::Connection` just as before. Then call the `add()` and `commit()` methods. You're done!

```
require 'rubygems'
require 'solr'
solr = Solr::Connection.new('http://localhost:8983/solr')
solr.add(:id => 123, :name => 'Fresh mozzarella cheese')
solr.commit()
```

More Information

For more information on solr-ruby, read the page at the Solr Wiki:

<http://wiki.apache.org/solr/solr-ruby>

MBean Request Handler

The MBean Request Handler offers programmatic access to the information provided on the [Statistics](#) and [Info](#) pages of the Admin UI. You can access the MBean Request Handler here: <http://localhost:8983/solr/admin/mbeans>.

The MBean Request Handler accepts the following parameters:

Parameter	Type	Default	Description
key	multivalued	all	Restricts results by object key.
cat	multivalued	all	Restricts results by category name.
stats	boolean	false	Specifies whether statistics are returned with results. You can override the <code>stats</code> parameter on a per-field basis.

Examples

To return information about the `CACHE` category only:

```
http://localhost:8983/solr/admin/mbeans?cat=CACHE
```

To return information and statistics about the `CACHE` category only:

```
http://localhost:8983/solr/admin/mbeans?stats=true&cat=CACHE
```

To return information for everything, and statistics for everything except the `fieldCache`:

```
http://localhost:8983/solr/admin/mbeans?stats=true&f.fieldCache.stats=false
```

To return information and statistics for the `fieldCache` only:

```
http://localhost:8983/solr/admin/mbeans?key=fieldCache&stats=true
```
